Derived from Ruthenium Complexes and  
Investigation of their Binding Mode**

Doctorial Thesis

by

Doris Marianne Burger

Für meine Familie

Diese Doktorarbeit entstand in der Zeit von März 2005 bis November 2008 am Institut für Analytische Chemie, Chemo- und Biosensorik an der Universität Regensburg.

Die Arbeit wurde angeleitet von Prof. Dr. Otto S. Wolfbeis.

Promotionsgesuch eingereicht am: 19.12.2008

Kolloquiumstermin: 02.02.2009

Prüfungsausschuss: Vorsitzender: Prof. Dr. Frank-Michael Matysik  
Erstgutachter: Prof. Dr. Otto S. Wolfbeis  
Zweitgutachter: Prof. Dr. Achim Wagenknecht  
Drittprüfer: Prof. Dr. Achim Göpferich

# Danksagung

Mein erster Dank gilt Herrn **Prof. Dr. Otto S. Wolfbeis** für die Bereitstellung des interessanten Themas, die stets anregenden Diskussionen und Hilfestellung bei Problemen bei meiner Arbeit und die hervorragenden Arbeitsbedingungen am Lehrstuhl.

Für die gute Laborgemeinschaft, die anregenden Diskussionen, die nicht immer nur einen wissenschaftlichen Hintergrund hatten danke ich meinen Laborkollegen **Petra Schrenkammer** und **Robert Meier**, der auch das Kulturelle im Labor nicht hat zu kurz kommen lassen. Außerdem möchte ich mich bei meinem Kommilitonen **Jochen Weh** und **Michael Linseis** bedanken, die mich durchs Studium begleitet haben und mit denen es nie langweilig wurde. Und bei **Christine Schmelzer** die uns Chemiker immer beim Mittagessen ertragen hat.

Weiterhin bedanke ich mich bei **Barbara Goricnik, Gisela Hierlmeier, Gisela Emmert, Edeltraud Schmid, Nadja Hinterreiter, Martin Link, Matthias Stich, Corinna Spangler, Christian Spangler, Simone Moises, Mark-Steven Steiner, Dr. Xiaohua Li, Katrin Uhlmann, Daniela Achatz, Heike Mader** und allen weiteren Mitarbeitern für die wissenschaftlichen und nicht wissenschaftlichen Diskussionen, die netten Kaffeerunden, Spielabende und die sehr gute Stimmung am Lehrstuhl.

Ferner möchte mich bei **Prof. Dr. Werner Kunz** bedanken für die Bereitstellung des Viskosimeters und bei **Bernhard Ramsauer** für die Hilfe bei den Messungen. Ebenso bei **Prof. Dr. Achim Wagenknecht** und seinen Mitarbeitern für die Hilfe bei der Aufnahme der Schmelzkurven.

Für die finanzielle Unterstützung während dieser Arbeit danke ich dem Graduiertenkolleg "**Sensorische Photorezeptoren in natürlichen und künstlichen Systemen**".

Abschließend möchte ich mich noch bei meiner Familie bedanken. Mein größter Dank gilt dabei meinen Eltern **Richard** und **Brigitte Burger**, die mir das Studium finanziert und mir immer mit Rat und Tat zur Seite gestanden haben. Und ganz herzlich bedanke ich mich bei all meinen Freunden, die mich immer unterstützt, abgelenkt und aufgemuntert haben, wenn es notwendig war.

# 1. Introduction

## 1.1 Ruthenium Ligand Complexes

### 1.1.1 Luminescence Emission Mechanism of Ruthenium Ligand Complexes

The term ruthenium ligand complexes (RLC) refers to complexes containing a ruthenium (II) ion as center ion and one or more diimine ligands. Their spectral properties arise from their unique electron states. The d-orbitals of the metal ion are split in three energetically lower (t) and two higher (e) orbitals in the presence of the ligands (Fig. 1.1.). The extent of the energy difference between the orbitals (t→e) is dependent on the crystal field strength  $\Delta$ .

**Figure 1.1.** Orbital state of metal ligand complexes. The d-orbitals are associated with the metal and are energetically split due to the crystal field of the ligands.

The six electrons of the ruthenium (II) fill the three d-orbitals with lower energies. Transition between the orbitals is formally forbidden. Although d-d transition occurs, the probability of the radiative transition is very low and the emission is quenched. d-d excited states are usually

unstable due to the fact that electrons in the e-orbitals are antibonding regarding the metal – ligand bonds.

In the described metal ligand complexes (MLC) a new transition occurs, involving a charge transfer between the metal, in this case ruthenium, and the ligand. Therefore, an electron is transferred from the metal to the ligand, the so called metal-to-ligand charge transfer transition (MLCT) (Figure 1.2.). This causes the intense absorption of the ruthenium MLCs near 450 nm.

**Figure 1.2.** Metal to ligand charge transfer (MLCT) transition.

Emission from these states is formally phosphorescence but is shorter lived than that of normal phosphorescence states. Due to spin-orbit coupling of the heavy metal atom, the normally forbidden transition to the ground state is more allowed, MLCs should have a short luminescence lifetime. After photoexcitation, the electrons undergo intersystem crossing from the singlet to the triplet MLCT state. This event proceeds rapidly and with high efficiency. Hence, the excited state decays by radiative and non-radiative pathways. The probability of non-radiative decay is higher than that of the radiative decay, so that the decay times are determined by the nonradiative decay rates. For a MLCT to be luminescent it is necessary that the MLCT state is located at a lower energy level than the d-d state. In the case of ruthenium ligand complexes (RLC) this criterion is fulfilled and the d-d levels are not accessible for radiationless decay. Therefore RLCs are highly luminescent.<sup>1</sup>

## 1.1.2 Features of Ruthenium Ligand Complexes

Ruthenium ligand complexes display several features that make them interesting for further investigations especially as biophysical probes. It was found that RLCs that contain nonidentical diimines, show strongly polarized emission. An increase of anisotropy is observed when they are conjugated to macromolecules such as proteins. Furthermore, RLCs display long lifetimes which increases upon binding to biomolecules.

RLCs absorb at a relatively long wavelength region, which is due to the MLCT transition. The broad absorption band at 450 nm (Figure 1.3.) shows extinction coefficients ( $\epsilon$ ) of 10000- 30000  $M^{-1} cm^{-1}$ . In the case of the presented RLCs the values for  $\epsilon$  are 15 000  $M^{-1} cm^{-1}$  for probe **1** and 32 000  $M^{-1} cm^{-1}$  for all presented dinuclear complexes. The absorption of the ligand occurs at 280 nm and is referred to as the the ligand centred (LC) absorption. The absorption by the metal via d-d transition is forbidden and therefore results in low extinction coefficients. Although the values of  $\epsilon$  of the MLCT transition are not comparable to that of fluorescein (35 -45000  $M^{-1} cm^{-1}$ ), they are in the range of many other fluorophores and sufficient for most applications.

**Figure 1.3.** Absorption and emission spectra of probe **1**.

The emission of RLCs occurs above 600 nm. In the case of the ruthenium complexes **1**, **2a-e**,  $\lambda_{max}$  is located at 610 nm (Figure 1.3.). In contrast to RLCs, the emission of lanthanide complexes is caused by a single atom but involves the complete complex. Further, the bonds between ligand and central ion are very strong, coming close to covalent binding.

Therefore, the RLCs are chemically very stable and the ligands do not tend to dissociate from the metal under any conditions required in synthetic organic chemistry, this leading to the ability to create a variety of designed compounds. Due to the large ligand field for ruthenium, ligand exchange requires higher temperatures but the resulting compounds are very stable. A systematic exchange of ligands while others remain is also possible. Another advantage of RLCs is the fact that they have a large Stokes' shift as shown in figure 1.3, which makes it simple to separate extinction and emission.

### 1.1.3 Applications

The investigation of ruthenium began with the introduction of the dinuclear complex  $[(\text{NH}_3)_5\text{Ru}_2\text{Pz}]^{2+}$  (pz is pyrazine) and the luminescent complex  $[\text{Ru}(\text{bpy})_3]^{2+}$  (bpy is 2,2'-bipyridine) in the late 1950s and 60s.<sup>2,3</sup> Polypyridyl complexes have been studied since with great interest due to their favourable photophysical and electrochemical properties. The enormous popularity originates also from the wide range of application offered. Extensive synthetic chemistry allows for systematic manipulation of their physical properties. No other metallic compounds except ferrocene show similar stability and flexibility. Melting points are continuously high and the complexes are often stable in solvents such as concentrated sulphuric acid. Although  $[\text{Ru}(\text{bpy})_2\text{Cl}_2]^{2+}$  and its analogues are often used as precursors, the development of new synthetic pathways enabled the preparation of tris heterolytic complexes and even complex multinuclear systems.<sup>4</sup> For purification of these compounds column chromatography, in particular HPLC, is frequently applied, but also ion exchange chromatography is widely used. Characterisation of the complexes is done via UV/Vis and emission spectroscopy, which in general is sensitive to the environment around the ruthenium centre. Mass spectrometry and elemental analysis was used as well. The structure can also be determined by crystal structure analysis or NMR spectroscopy.<sup>5</sup> Normally, high quality spectra can be achieved, but with increasing complexity the number of NMR signals increase and will overlap.

In the mid 1970s it was found that  $[\text{Ru}(\text{bpy})_3]^{2+}$  immobilised on a glass slide was able to split water in oxygen and hydrogen using sunlight. Although, it was shown later that the supposed photochemical water splitting did not occur in highly purified samples, the design of ruthenium complexes which are able to photoinduce the splitting of water became a very active area of research.<sup>6,7</sup> A lot of compounds were synthesised to improve their photostability

and photoinduced energy transfer. The introduction of nanocrystalline TiO<sub>2</sub> surfaces modified with monolayers of ruthenium complexes finally led to a stable and efficient conversion of solar energy to electricity without sacrificing donors.<sup>8,9</sup>

Besides, ruthenium complex containing polymers were developed. Their photophysical and electrochemical properties were investigated, resulting in the development of electrochemical sensors and biosensors.<sup>10,11</sup> Electrochemical studies on the effect of temperature, electrolyte concentration, crosslinking and layer thickness were made resulting in a better understanding of the charge transfer in these thin layer materials that led to the employment of electrodes coated with those polymers as electrochemical sensors.<sup>12,13,14</sup> Analytes such as nitrite,<sup>15</sup> nitrate<sup>16</sup> and ascorbic acid were determined. Furthermore, enzymes were incorporated into the polymer layer to detect analytes such as glucose.<sup>17</sup> The redox potential is controlled by the metal centre but the polymer layer controls the kinetics and thermodynamics of the charge transport through the layer. Therefore, charge transport rates, activation energies and catalytic behaviour depend on the ambient electrolyte and the results are dependent of the measurements conditions.<sup>18</sup> Due to the stability of those complexes and their adaptable redox potentials, they can be modified with thiol or pyridine groups and immobilised on gold and silver electrodes to investigate their electrochemical properties.

The emitting properties of ruthenium complexes embedded in polymer layers were successfully applied in the development of electro-luminescent devices. Furthermore, the long lifetimes of ruthenium polypyridyl complexes were used in the development of luminescence sensors, in particular for oxygen.<sup>19</sup> The oxygen concentration is related to the emission intensity or lifetime.<sup>20</sup> Here, the complexes are mostly immobilised in a solid matrix such as polymers by either electrostatic interactions or by covalent bonds.<sup>23,21</sup> Good results were obtained by embedding the complexes in sol-gel type layers.<sup>22</sup> Optical fibers<sup>23,24</sup> and microtiter plates<sup>25</sup> were coated with those sol-gel layers to achieve very simple, cheap and flexible sensors. The thickness of the layer and the porosity of the layer can be varied by coating parameters.<sup>20</sup> It is important to mention that the photophysical properties are influenced by the matrix itself.<sup>26</sup> The same approach was applied to develop sensors for pH,<sup>27</sup> temperature<sup>28,29</sup> and CO<sub>2</sub><sup>30</sup>.

The emission properties of ruthenium complexes were also used to detect anions by attaching anion recognition groups to the ligands.<sup>31</sup> The binding of cations was also investigated by the introduction of binding sites like crown ethers, EDTA or other similar groups.<sup>32</sup>

A further field of interest in the investigation of ruthenium complexes is the study of their interaction with nucleic acids. The binding of the enantiomers of RLCs to DNA were investigated.<sup>33</sup> The enantiomers of ruthenium complexes bind to DNA in two different binding modes.<sup>34</sup> This enantiomeric selectivity is valuable in designing structural probes for DNA.<sup>35</sup>

The strength and binding mode of the complexes to DNA differs with the ligands attached to the centre.<sup>36</sup> Although all cationic compounds are supposed to bind through electrostatic forces to the negatively charged DNA, the planar extended aromatic polypyridyl ligands could also insert between the base pairs of B-form double stranded DNA. This is known as intercalation. The theory was proven by the fact that  $[\text{Ru}(\text{bpy})_3]^{2+}$  binds only weakly to DNA through mainly electrostatic interaction whereas the interaction with  $[\text{Ru}(\text{phen})_3]^{2+}$  is much stronger. Topoisomerase assays were performed to demonstrate the partial intercalation of the phenanthroline ligand by the unwinding of the DNA helix.<sup>37</sup> Later, the binding was studied in more detail via hydrodynamic and chiroptic methods.<sup>38</sup> Other ligands were introduced and their binding abilities to DNA investigated. One of these ruthenium complexes was  $[\text{Ru}(\text{bpy})_2(\text{HAT})]^{2+}$ , where HAT is 1,4,5,8,9,12-hexaazatriphenylene. It was shown that this complex intercalates between the base pairs. However, the best effect in increasing the size of the ligand was achieved with the introduction of the dppz ligand (dppz = dipyrido[3,2-a:2'3'-c]phenazine). Remarkably, the complex  $[\text{Ru}(\text{bpy})_2(\text{dppz})]^{2+}$  behaves as a light switch for DNA. The complex shows no luminescence in water, but emits strongly in non-polar solvents and in the presence of DNA.<sup>39</sup> The photophysical behaviour of such dppz complexes in absence and presence of nucleic acids was studied in luminescence and absorption measurements as well as in hydrodynamic studies.<sup>40</sup> Ruthenium complexes with an analogous dipyridoquinoxaline (dpq) ligand are, in contrast, luminescent in water.<sup>41</sup> If the dpq is substituted with an amide, the complex becomes non-luminescent in aqueous solution. But it still emits strongly in non-polar solvents and in presence of DNA even with a higher efficiency than  $[\text{Ru}(\text{bpy})_2(\text{dppz})]^{2+}$ .<sup>42</sup>

A further change of the photophysical and photochemical properties of polypyridyl complexes is observed if phenanthroline is exchanged by 1,4,5,8-tetraazaphenanthrene (TAP) or HAT. It was shown that  $[\text{Ru}(\text{TAP})_3]^{2+}$  is able to form a photoadduct with DNA. This behaviour is due to the oxidising potential of the excited state.<sup>43</sup> Complexes such as  $[\text{Ru}(\text{bpy})\text{L}_2]^{2+}$  or  $[\text{Ru}(\text{L})_3]^{2+}$  (L = HAT or TAP) show the same behaviour towards DNA, but the mono substituted complexes  $[\text{Ru}(\text{bpy})_2\text{L}]^{2+}$  do not.<sup>44</sup> The excited states could specifically oxidise guanine either as the free nucleotide (5'-GMP) or in DNA, the other bases remain

unaffected. The photoadduct of  $[\text{Ru}(\text{TAP})_3]^{2+}$  was isolated and identified.<sup>45</sup> The product of the photoreaction of  $[\text{Ru}(\text{TAP})_2(\text{bpy})]^{2+}$  with DNA is unusual because of the formation of a direct bond between the TAP ligand and the amino group of the guanine.<sup>46</sup> Kirsch de Mesmaeker et al. also proved the reaction between the HAT ligand of  $[\text{Ru}(\text{HAT})(\text{phen})]^{2+}$  and the O atom of the guanine moiety.<sup>47</sup> Moreover, complexes such as  $[\text{Ru}(\text{TAP})_2(\text{dppz})]^{2+}$  were synthesised to combine the strong intercalative binding to DNA with oxidising power.<sup>48</sup>

The well established synthetic pathways are valuable for design and preparation of ruthenium polypyridyl complexes for a wide area of applications such as biosensors and optical displays. It is even possible that the complexes act as the active ingredient in phototherapeutic procedures.

## 1.2 Binding Modes

Three binding modes to DNA exist. A molecule can be associated to the nucleic acid by (a) electrostatic interaction, (b) minor or major groove binding or (c) intercalation (see Figure 1.4.).<sup>49</sup> In case of electrostatic binding of the dye to DNA, it binds to the phosphate backbone of the nucleic acid. Groove binding and intercalation result from an assembly based on  $\pi$ -stacking, hydrogen bonding, van der Waals, or hydrophobic interactions. In each case, the binding is induced by the transfer of the hydrophobic DNA binder from the aqueous solution in the lipophilic environment of the DNA

**Figure 1.4.** Electrostatic binding (a), intercalation (b) and groove binding (c) of a probe to DNA.

Groove binding occurs in either the minor or the major groove of the DNA. Large molecules such as proteins preferentially bind in the larger major groove. Smaller probes prefer binding in the minor groove.<sup>50</sup> The grooves of the DNA are formed by the edges of the nucleic bases that face into the groove and the phosphate backbone of the DNA. Groove binders usually consist of at least two aromatic or heteroaromatic rings connected by a flexible bond that allows conformational flexibility to match into the groove.<sup>51</sup> Typical minor-groove binders are polyamides<sup>52</sup>, Hoechst 33258<sup>53</sup> and netropsin<sup>54</sup>.

If the probe intercalates between the base pairs, however, the binding mode is called intercalation. Typical intercalators have planar polycyclic aromatic rings which can intercalate between the nucleic bases which are in an almost coplanar arrangement. The interaction is driven by electrostatic factors, dipole-dipole interactions and  $\pi$ -stacking of the probe with the DNA bases.<sup>50</sup> Furthermore, an external positive charge appears to be necessary for intercalation because small compounds such as naphthalene or quinoline intercalates only in DNA if there are positive charges in a substituent side chain.<sup>55</sup> The influence of the positive charge on the intercalation decreases with the increase of the aromatic system. The balance between the forces that control the ability of a molecule to intercalate is obviously delicate.

Other than groove-binding, intercalation influences the DNA structure, because the DNA has to unwind so that the intercalator fits between the base pairs. This unwinding results in a lengthening of the DNA strand and increases the space between the phosphate groups of the backbone.<sup>56</sup> Thus, the negative charge density along the helix is decreased. Positively charged probes lead to the release of counter cations from the DNA upon their addition, so the addition of cationic probes is favorable over uncharged compounds. Furthermore, the binding of one intercalator hinders the access of other intercalator molecules to binding sites in close proximity. Probably this is caused by the structural change of the DNA by intercalative binding, which leads to the sterical hindrance of the neighbouring binding sites.<sup>57</sup> The reduction of the negative electrostatic potential of the DNA by intercalation additionally results in a minimised electrostatic attraction of the cationic probe to this site. Typical binding constants for intercalation of dyes into DNA range from  $10^4$  to  $10^6 \text{ M}^{-1}$  and are usually smaller than that of groove binders ( $10^5$  to  $10^9 \text{ M}^{-1}$ ).<sup>50</sup>

Due to the fact that intercalators have a tendency to show very short residence times (time within the dye is located between the base pairs) within the intercalation binding sites, derivatives were designed, containing two or more intercalative moieties to overcome this problem. The dissociation constant significantly decreased with this approach. The intercalating functionalities are linked in general by an alkyl chain. The structure of the

complex formed between bisintercalator and DNA is dependent of the length of linker. Short alkyl chains ( $< 9 \text{ \AA}$ ) lead to monointercalation, whereas bisintercalation takes place with longer connections ( $> 10.2 \text{ \AA}$ ) between the intercalating parts without a violation of the neighbour exclusion principle.<sup>58</sup> Theoretically, the binding constants of a bisintercalator should be the square of that of the corresponding monomer, but experimental data are much smaller than predicted, probably due to unfavourable geometrical effects.<sup>57</sup>

The properties of DNA and probe change significantly upon binding. This can be used for the determination of these properties and to quantify and to investigate the binding process of a given DNA probe. Viscosity or sedimentation coefficients,<sup>59</sup> melting temperatures of DNA,<sup>60</sup> mass-spectrometric data,<sup>61</sup> NMR shifts<sup>62</sup> and the absorption and emission properties can be employed for this purpose. The absorption of circularly and linearly polarized light used in circular and linear dichroism spectroscopy can be used to determine the orientation of the dye molecule relative to the DNA.<sup>63</sup> Steady state fluorescence polarization measurements as well as lifetime studies contribute to elucidate the binding mode.<sup>64</sup> Binding constants are obtained from absorption or fluorescence titration, equilibrium dialysis or DNA footprinting experiments.<sup>36</sup> The choice of methods to determine the binding mode have to be made carefully and only a combination of different methods provides sufficient information to determine the binding mode. Therefore, the structure of the probe has to be considered, especially if different binding modes are possible or if the probe may bind to more than one binding site.

### **1.3 Motivation and Aim of Work**

The DNA is carrier of the genetic information of the cell. Therefore, detection and quantification of nucleic acid plays an important role in a variety of biological applications. Applications range from accurate measurements of DNA yields before cloning, detection of nucleic acids in drug preparation, quantification of dsDNA in nuclease assays and polymerase chain reaction products to the identification of bacteria or growth of cell cultures. The DNA molecule offers several binding sites for a large number of guest molecules.. In addition, the physical properties of the probe change upon binding to DNA, which allows detection of DNA by monitoring the changes. Especially popular is the use of DNA staining with fluorescent dyes. The change of color and intensity upon binding to DNA are measured. These probes have to be very selective with high binding constants. A variety of organic dyes

were designed to meet the requirements. Special attention was paid to intercalators such as ethidium bromide, the Hoechst dyes or the TOTO and YOYO dyes. The TOTO and YOYO dyes serve as template for the ruthenium complexes synthesised in this work. The TOTO dye is a dimer, in which the two cyanine moieties are linked through an aliphatic chain containing quaternary nitrogen atoms (see Figure 1.5.). The organic fluorescent dyes suffer from some disadvantages. The small Stokes' shifts makes it difficult to separate excitation and emission light. The lifetimes are very short (in the range of a few ns) and organic dyes show no or less anisotropy.

**Figure 1.5.** Chemical structure of TOTO-3.

In this work, ruthenium ligand complexes (RLC) were synthesised mimicking the TOTO and YOYO dye structure to improve their binding strength to DNA and employ the spectral and physical properties of RLCs. To show the improvement of the binding between the complexes and DNA, the binding mode was examined. Furthermore, a new assay to quantify nucleic acid is presented using the technique of resonance light scattering technique (RLS). It is a simple and sensitive method to detect biomolecules such as DNA. In this work, the nucleic acid concentration was determined in the nanogram level under physiological conditions. The sensitivity and selectivity is comparable with common luminescent methods.

## 2. Resonance Light Scattering Technique (RLS)

### 2.1 Introduction of the RLS Technique in Analytical Chemistry

Every heterogenic system situated in an electromagnetic field can scatter light. The scatterer could be either a single molecule or self-aggregates or self-assemblies of a few or a large number of molecules. The light is scattered in all directions except that of the incident electromagnetic wave.<sup>1,2</sup> According to the electromagnetic theory, scattered light originates from electrons of the scatterer which were accelerated and set in oscillatory motion by the excitation of an incident electromagnetic wave.<sup>1,2</sup>

Since all systems except for a vacuum are more or less heterogenous, light scattering is a widely spread phenomenon, for example observable in rainbows or sunrises. In fluorescence spectroscopy, light scattering is regarded as one of the major interferences and was tried to be minimized. In 1993, Pasternack et al. observed that by scanning both monochromators of a conventional fluorescence spectrophotometer synchronously, the light scattering signals of trans-bis(N-methyl-pyridinium-4-yl)-diphenylporphyrine and its copper(II) derivatives increased several orders of magnitude in the presence of DNA.<sup>3</sup> The RLS technique, unlike conventional Rayleigh scattering, focuses on the enhancement of light scattering signals near or within absorption bands.<sup>4</sup> It shows a good selectivity and high sensitivity.<sup>5</sup> RLS signals can be measured using a common fluorescence spectrophotometer whereas in the most other methods using light scattering a laser as light source is required.<sup>6,7,8</sup>

Most of the scatterers in RLS investigations are supposed to be in the Rayleigh range, therefore the RLS is often named resonance Rayleigh scattering (RRS). RLS is attributed to elastic light scattering, still including signals of quasi-elastic light scattering, Brillouin scattering and fluorescence.<sup>9</sup>

After the establishment of the RLS technique in analytical chemistry, its theory was discussed and further development of the RLS technique was done. A significant achievement was the development of RLS particles as well as the derived techniques including the total internal reflectance resonance light scattering (TIR-RLS), backscattering light (BSL), resonance light scattering imaging (RLSI), flow injection resonance light scattering (FI-RLS) and wavelength ratiometric RLS (WRRLS).

Before 1995, the RLS technique was only used for characterization of self-aggregation and self-assemblies.<sup>10,11</sup> But after the first promising results, the RLS technique was soon extended to other purposes. Liu et al. used the technique to study ion association complexes,<sup>12</sup> but it was found that not only ion-association reactions can be characterized, also trace amounts of metal ions can be determined.<sup>13,14</sup>

Then, in 1996 and 1997, Li et al first applied the RLS technique in biochemical assays.<sup>15,16</sup> Nucleic acids could be determined satisfactorily and not only with probes with large ring systems like porphyrins.<sup>17,18</sup> Once the use of RLS signal for analytical purposes was established and proven to show good results, the technique was more and more applied in analytical chemistry.

## 2.2 Theory of Resonance Light Scattering according to Pasternack et al.

In general, all experiments that are performed by scanning both monochromators simultaneously on a fluorescence spectrophotometer are termed as RLS. However, according to theory of Pasternack et al. this is not always applicable.<sup>3,9,10,11</sup> The enhancement of scattered light has to be in close proximity of an absorption band to be regarded as a RLS signal. A signal is ascribed to RLS if the enhanced light scattering peak is near or within an absorption band of the system. Some scattering systems where the signal increase results from Rayleigh scattering or large particle scattering and is therefore independent of absorption bands, showed the same performance as RLS systems.

For understanding RLS, the aggregate is regarded as a particle with a refractive index different from that of the surrounding medium. If the size of the particle is less than 20 fold of the wavelength of the incident light, and the ratio of the refraction index of the sphere and the environment is not too large, the scattering can be described as Rayleigh scattering. The extent to which a particle absorbs and scatters light depends on its size, shape and refractive index relative to the surrounding medium (both real and imaginary part). The scattering and absorption efficiencies are given by the scattering and absorption cross section.

$$C_{sca} = (\pi r^2) \left( \frac{8}{3} \right) (x^4) \left| \frac{m^2 - 1}{m^2 + 2} \right|^2 \quad (2.1)$$

$$C_{abs} = (\pi r^2) 4x \operatorname{Im}\left\{(m^2 - 1)/(m^2 + 2)\right\} \quad (2.2)$$

where  $r$  is the radius of the sphere,  $\operatorname{Im}$  the imaginary part,  $m$  the complex refractive index which was introduced in study of Rayleigh scattering near absorption bands and  $x$  is the size parameter, equal to  $(2\pi r n_{med}/\lambda)$  where  $\lambda$  is the incident wavelength and  $n$  the refractive index of the medium. Near a spectral maximum, the real part of  $m$  varies and the imaginary part of  $m$  increases, resulting in an increase of absorption and scattering cross section. Due to the fact that the scattering is a much stronger function of  $m$ , an enhancement of scattering is observed near or within absorption bands.

Although enhanced light scattering signals are expected due to an increase of  $m$  when  $\lambda$  reaches an absorption maximum, they are difficult or impossible to detect because of the increased absorption and the weakness of the enhanced scattering effect. However, when self aggregates or self assemblies of chromophores occur, the enhancement of the RLS scattering can be enormous. To imply self aggregation and self assemblies in the explanation of RLS was an innovative and important factor and is different from RRS research before 1993. The reason that the aggregation is an important factor in the enhancement scattering signals is the fact that the amount of absorption  $A(\lambda)$  and scattering  $I_{sca}$  depend on size of the aggregate in two different ways.  $I$  and  $A(\lambda)$  for a spherical scatterer of a ample thickness  $L$  can be calculated via the following expressions:

$$I_{sca} = C_{sca} \left(\frac{N}{V}\right) I_0(\lambda_0) = \frac{24\pi^3 v n_{med}^4 I_0(\lambda_0)}{\rho \lambda_0^4} \left(\frac{m^2 - 1}{m^2 + 2}\right)^2 = Kc \quad (2.3)$$

$$A(\lambda_0) = 2.303^{-1} \left(\frac{N}{V}\right) C_{abs} L = 2.303^{-1} \left(\frac{m'}{\rho V}\right) \frac{6\pi \cdot n_{med}}{\lambda_0} \operatorname{Im}\left(\frac{m^2 - 1}{m^2 + 2}\right) \quad (2.4)$$

where  $N/V$  is the number of scatterers per volume,  $m'$  the mass of the scatterer,  $\rho$  the density of scattering material,  $I_0(\lambda_0)$  the incident intensity and  $M$  and  $c$  the molar mass and concentration of the scattering material. In a system with fixed concentration, the absorption due to each sphere per unit volume is inversely related to the volume of the sphere. The amount of absorption is independent of the size of the spheres. The Beer-Lambert law implies this since the absorption for a fixed path length should only depend on the

concentration of the material in the sample and nothing else. Besides, the scattering due to each sphere is proportional to the square of the volume. Since the number density of spheres depends inversely on the volume, the amount of scattering is directly proportional to the volume of each sphere. Thus, the larger the aggregate the greater is the scattering.

Rayleigh scattering depends on the inverse fourth power of the wavelength ( $C_{\text{sca}} \propto \lambda^{-4}$ ) and the absorption depends only on the inverse wavelength ( $C_{\text{abs}} \propto \lambda^{-1}$ ), if the refractive index does not vary with the wavelength. To investigate the wavelength dependency, experiments were performed out of the range of absorption bands. It was shown that the enhancement of scattering at wavelengths within the absorption bands, is due to changes in  $n$  and, to a minor account, results from changes of the wavelength. Aggregates were always regarded as spheres, which is a major simplification. However, calculations of Pasternack et al. give evidence that as long as the wavelength is much greater as the dimension of the nonspherical aggregates and these aggregates are randomly distributed in the medium, the absorption and scattering cross section are only weakly dependent of the shape.

Hence,  $m$  increases in such scattering systems when the incident light comes near absorption bands, resulting in a maximum for the scattering cross section, whereas the absorption cross section remains unperturbed. The RLS signal is dependent of the size of the aggregate. An enhancement of the RLS signal is expected when there is an obvious enlargement in volume in the presence of the analyte. This ensures that the experiment can be performed on a common spectrofluorimeter.

In addition, it is important that the chromophores can interact with the analyte. That requires compatibilities in structural and physical properties, such as symmetry, charges, solubility, pH and ionic strength. The research is focused on small organic molecules or metal nanoparticles. Recently, more application fields have been developed, such as microarrays, microfluidics or cell surface components as analytes, DNA hybridization arrays and protein as well as enzyme functionality. Most assays are performed under a right angle geometry. Experiments using a different angle between incident and scattered light have been attempted to disclose the analytical potential of RLS technique. Instrumental properties, especially the lamp intensity at any wavelength influences the RLS signal and there is no satisfactory correction procedure to solve this problem. Furthermore, RLS assays are time consuming because of the lack of automation in the input of the samples and the measurement and the large number of samples that are necessary.

## 2.3 RLS Techniques

### 2.3.1 RLS Imaging Technique

With the common RLS technique, it is only possible to receive an average light scattering signal of aggregates in bulk solutions or at oil/water interfaces, it fails however to observe a single scatterer. To overcome this limitation and to obtain a new biomedical imaging technique for managing problems with cells, tissues and organs for diagnostic purposes of diseases, the RLS imaging technique was established. Yguerabide et al. used RLS Particles<sup>TM</sup> for their application, because of their extremely high light scattering power. A 60 nm gold particle, regarding to the light-emitting power was equivalent to  $3 \times 10^5$  fluorescein molecules. Therefore, a lamp is sufficient as light source and a standard scanner with a charge coupled device (CCD) camera can be used.<sup>2</sup> RLS Particles produce stable and strong signals and the scattering wavelength can be tuned via particle size.<sup>49</sup> In addition, RLS Particles can functionalised easily to improve specific binding for applications in simple as well as in complex systems.<sup>55, 56</sup> In contrast, Huang et al. investigated small organic molecules (SOMs) as scatterers. Due to their worse scattering efficiency, a laser is applied as light source. A single aggregation of TPPS<sub>4</sub> induced by proteins could be observed at a right angle to the excitation beam with a CCD camera in situ because the RLS signals are more intense due to laser excitation than those measured with a spectrofluorimeter.<sup>19</sup> Each count of aggregated species in these images is proportional to the concentrations of BSA and HSA in the range of nanograms, indicating that RLSI is a very sensitive method. RLSI technique was also used for DNA and saccharide detection with comparable sensitivities.<sup>20, 21, 22</sup> However, the RLS imaging technique is limited by the instability induced by Brownian motion, causing fluctuation of the signal of the scatterer in the detection range. Hence, RLSI with SOMs is often combined with TIR-RLS technique where the scatterer can be immobilised or controlled at the liquid-liquid interface for imaging. DNA is selectively absorbed by triocetyl oxide (TOPO) at the water-oil interface. The resulting signals can be observed by a common microscope.<sup>23</sup> Thus, combination of total internal reflection resonance light scattering technique (TIR-RLS) and the imaging technique minimize the problem of weak electrostatic or hydrophobic interaction between analyte and scatterer which are easily disturbed by other substances.

### 2.3.2 Backward Light Scattering (BLS)

In general, RLS signals are detected in a right angle to the incident light beam. However, forward and backward scattering is being neglected. The scattering light intensity of a spherical particle illuminated by a monochromatic light beam is angle dependent according to the Rayleigh theory.<sup>2</sup> In backward direction it is two times greater than in the right angle direction. The theory of backward light scattering (BSL) is related to the theory of TIR-RLS and is also based on scattering at oil/water interfaces. The distinct difference between them is that the scattering angle is above 90° in the BSL technique. The (TPP)-Al(III)-DNA complex, formed at a water/CCl<sub>4</sub> interface, was determined under a scattering angle of 107 °.<sup>24</sup> Huang et al. improved the optical assembly and succeeded in measuring the amphiphilic species of quercetin-cetyltrimethylammonium bromide adsorbed at a water/CCl<sub>4</sub> interface at a scattering angle of 154°.<sup>25</sup> Scattering signals increase with the angle ranging from 90° to 180° when other conditions were kept stable.<sup>2</sup> Hence, the BSL technique is expected to show higher sensitivity. The LOD of DNA is determined to be 0.16 ng mL<sup>-1</sup> in the presence of Eu(III) and TOPO with the TIR-RLS method,<sup>26</sup> but a LOD of 16 pg mL<sup>-1</sup> for DNA with the system Al(III) and TPP was calculated with the BSL technique.<sup>24</sup>

This method is, in fact, a good alternative if the apparatus is available. Backward light scattering spectroscopy has been used to provide structural and functional information of tissue in the fields of biomedical and biophysical sciences.<sup>27,28</sup> It is a promising technique to perceive pre-cancerous and early cancerous changes in epithelial cells.<sup>29</sup> Heavy metal ions in environmental water and chloride ions in human urine were determined with this method with higher sensitivity than with the common RLS technique.<sup>30,31</sup> The BSL method, used either in bulk solution or at liquid-liquid interfaces, is a promising new method.

### 2.3.3 Total Internal Reflection Resonance Light Scattering (TIR-RLS)

The total internal resonance light scattering technique depends on the formation of an amphiphilic species at a liquid-liquid interface. Such an amphiphilic species can be achieved through an interfacial interaction between a water soluble compound and an oil soluble compound or through interaction of substances with surfactants which are known to be located at water/oil interfaces. The selective adsorption of the analyte in the interface region minimises the disturbances from interfering substances in the sample and the method shows a

higher sensitivity because of the enrichment of the analyte at the water oil interface.<sup>32</sup> The LOD of DNA was determined to be  $0.25 \text{ ng mL}^{-1}$  at a water/tetrachloromethane interface in the presence of acridine orange and CTMAB via TIR-RLS.<sup>33</sup> The chemical or biological molecules can be highly selective. The interaction of immiscible substances can be studied, as well as the orientation of amphiphilic substances at the water/oil interface. In combination with RLS imaging and backward light scattering, the liquid-liquid interface shows a high potential for investigation of the interaction of dyes with biological macromolecules.<sup>23, 34</sup>

### **2.3.4 Flow Injection Resonance Light Scattering (FIA-RLS)**

The main advantages of flow injection analysis are reproducibility and automation. In addition, systems can be investigated away from their physical or chemical equilibrium. FIA has been combined with a lot of detection methods, such as fluorometry, chemoluminescence and electrochemoluminescence. Fernandez et al. first combined flow injection analysis with Rayleigh light scattering to determine the total protein concentration in a real sample.<sup>35</sup> Using Biebrich scarlet as probe, it was possible to determine BSA via FIA-RLS down to  $7.8 \text{ ng mL}^{-1}$ . The method was successfully applied to quantify of total protein concentration in human serum samples. FIA-RLS is an improvement over conventional RLS techniques because of its better reproducibility. Additionally, time consuming laborious operations are decreased and the required amount of sample is reduced.<sup>36, 37</sup>

### **2.3.5 Surface Enhanced Light Scattering (SELS)**

The RLS technique on water/oil interfaces could also be applied to solid surfaces like a glass slide, because they show similar properties as the liquid-liquid interfaces. Therefore, glass slides could be used to investigate interactions occurring at the surface. The light scattering of a glass slide coated with antigen is enhanced by the binding of the antibody. By scanning simultaneously the excitation and emission monochromators of a common spectrofluorometer, the increased RLS signals of the surface are measured, resulting in an optical immuno-sensor. This sensor has a high specificity under optimal conditions and other proteins like BSA shows no interferences corresponding to the specific antigen-antibody

binding. Besides, the high sensitivity of the RLS technique and the particular selectivity of immuno reactions, the assay is simple, fast and reproducible.<sup>38</sup> It could be applied to the determination of various proteins due to the enhanced RLS signals of the surface, which is coated with the corresponding antigen. Furthermore, surface enhanced light scattering technique (SELS) was used for a rapid optical detection method of pathogens and DNA hybridization assays.<sup>39</sup> Using gold nanoparticles the required amount of sample was reduced and the microarrays could be achieved without bleaching and thereby allowing re-scanning at a later time.<sup>40, 41</sup>

### **2.3.6 Wavelength-Ratiometric Resonance Light Scattering (WR-RLS)**

In common RLS measurements, the amount of analyte was determined at the wavelength where the maximum RLS signal was achieved. Unfortunately, fluctuations of the RLS intensity arise from environmental conditions like the incident light intensity and medium conditions such as pH, ionic strength and temperature. Due to this problem of RLS technique, real time measurements of the investigated system to obtain dynamic data are not conventional. Based on the well established method of ratiometric fluorescence measurements, RLS ratiometric resonance light scattering was developed to compensate the disadvantages of common RLS measurements mentioned above. Lakowicz et al. first reported the ratiometric RLS method using gold or silver colloid aggregation.<sup>42</sup> The ratio of scattered intensities at two incident wavelengths is measured. The benefits of this method are the independency of the total concentration of the probe, the measurements are more precise and show a good reproducibility with a wide linear range.<sup>43, 44</sup> Furthermore, the analysis of the data of the ratiometric method provides more reliable information of the signal.

## **2.4 New RLS Probes**

There are a large number of assays using small organic molecules (SOM) as probes to detect and study their interactions with large biomolecules such as proteins and DNA.<sup>45, 46, 47,</sup><sup>48</sup> However, metal nanoparticles have been found to scatter light highly efficient and with great stability. These spherical nano-sized colloidal metal particles, in general silver and gold particles, were described as RLS particles<sup>TM</sup>.

They show special optical properties due to the excitation of the collective oscillations of conducting electrons known as surface plasmons resonance. The resonance frequency depends on the size, shape and dielectric environment of nanoparticles. Thus, the color of scattered light can easily be changed by varying their size, composition or structures.<sup>49</sup> Gold nanoparticles display different colors only depending on their diameter. This property makes it possible to use the particles in multicolour assays.<sup>50</sup> Another benefit of RLS particles is that they produce a very stable signal. In contrast to SOMs, particles, although exposed repeatedly or continuously to intense light, do not suffer neither from photobleaching, nor from quenching and decaying.<sup>51</sup> Therefore, stable signals with a high reproducibility can be obtained in assays.<sup>40</sup>

The RLS particles were used to determine DNA and proteins.<sup>52, 53</sup> Using silver nanoparticles and CTMAB as probe, the RLS intensity of the nano Ag-CTMAB complex decreases in presence of DNA and a LOD of  $4,8 \text{ ng mL}^{-1}$  for ct-DNA was found.<sup>54</sup> In addition, the particles can be coated with different substances utilising thiol and amine chemistry, like antibodies, DNA probes and ligands to functionalise the particle to receive a specific binding to analytes, particularly in clinical and biological assays.<sup>55, 56, 57, 58, 59</sup> The RLS intensity of gold nanoparticles functionalized with goat antigen human IgG is greatly enhanced in the presence of human IgG. A limit of detection of  $10 \text{ ng mL}^{-1}$  could be reached. This immunoassay can be accomplished in a homogeneous solution with an one-step operation within 10 min and has been successfully applied to the determination of human IgG in serum samples, in which the results are in good agreement with those of the enzyme-linked immunosorbent assay (ELISA), indicating its high selectivity and practicality. Due to their extremely high brightness, particles scatter light very efficiently which increases the sensitivity compared with SOMs.<sup>41</sup> The concentration of the probe in the assay can be much smaller in the case of particles due to high scattering efficiency. In hybridisation assays it has been shown that the specific signal from microarrays obtained by RLS hybridized samples is 3 times higher than that of Cy 3 labelled ones. Therefore, it is possible to measure lower amounts of input RNA using the RLS technique, whereas using the Cy 3 labelled target yields no detectable signal.<sup>40</sup>

## 2.5 Application and Future of the RLS Technique

Besides UV/Vis absorption, fluorescence and circular dichroism spectroscopy, resonance light scattering techniques have become a further method to investigate aggregation of chromophores such as porphyrins.<sup>60, 61, 62</sup> The light scattering technique is used to quantify analytes like nucleic acids,<sup>63,64,65,66,67,68,69,70,71,72,73</sup> proteins,<sup>74,75,76,77,78,79,80</sup> pharmaceuticals,<sup>81</sup> inorganic ions and surfactants. It was also successfully applied to immuno assays and DNA hybridization.<sup>57, 82</sup> Hence, the technique proves its applicability to clinical and biological assays.<sup>83, 84</sup>

Although RLS technique is very sensitive and simple, it suffers from low selectivity. However, a lot of improvements were made to overcome this problem. RLS probes with high affinity to their analytes were developed. New RLS probes that show high signals when bound specifically to an analyte are of great interest in the evolution of RLS techniques. RLS particles have a great potential as contrast agents to provide anatomic details of cells and tissue architecture, which is an important factor for diagnostic purposes. The use of fluorescent dyes is limited due to their photobleaching and cytotoxicity. RLS particles like gold nanoparticles are a good alternative because of their high scattering efficiency, the resistance against photobleaching and chemical and thermal denaturation. Furthermore, the cytotoxicity depends on the size of the material. The strong light scattering of gold nanoparticles has been of use in real optical imaging of pre-cancer by using confocal reflectance microscopy.<sup>85</sup> El-Sayed et al. have demonstrated the possibility to distinguish between non-cancerous and cancer cells by dark-field light scattering imaging of solid 40 nm gold nano particles immunointegrated to epidermal growth factor receptor (EGFR) overexpressed on cancer cells.<sup>86</sup> The fact that RLS particles can be modified easily on the surface to improve their specific binding, makes them additionally interesting for biological and clinical applications.<sup>87, 88</sup> Applications based on light scattering signals of RLS particles have a promising future in cellular and biological imaging.

Most of the present analytical RLS applications are based on homogeneous assays in solution, but heterogeneous assays, for instance, on microarrays were especially useful in high throughput screening and are less time consuming. Hence, RLS technique on planar surfaces, like microwells could provide parallel detection of a wide range of biomolecules like nucleic acids, proteins, lipids and carbohydrates for monitoring or diagnostic purposes. Development of instruments that allow RLS measurements with angles which differ from 90° would be very useful. Although there are already techniques that have resolved the orthogonal

geometry between incident light and scattered light like forward and backward scattering RLS technique, they still have to be measured at a fixed angle. An angle scanned RLS technique provides the possibility to work with thin films.

RLS technique eventually may be combined with other methods like capillary electrophoresis or high performance liquid chromatography (HPLC) as new detection method besides the well established UV/Vis or fluorescence spectroscopy. With the wide application in biochemical and environmental analysis, immunoassays and the possibility to combine them with other analytical methods, the RLS techniques have great potential to become important tools in analytical chemistry.

# 3. Investigation of Binding Mode of the Probes to DNA

## 3.1 Introduction

One important aim when investigating the properties of new DNA probes is to determine their binding mode. It has been shown that certain ruthenium ligand complexes (RLCs) have three kinds of noncovalent binding modes to DNA which are electrostatic binding, intercalation or groove binding.<sup>1,2</sup> Some RLCs can induce DNA cleavage upon irradiation either by producing singlet oxygen or via electron transfer, and thus acting as photochemical endonucleases.<sup>3,4</sup> Therefore, they can be regarded both as probes for nucleic acid and as therapeutic agents. It has been shown that the specificity of the photochemical reactivity is enhanced with increasing affinity of RLC to DNA. Hence, the photochemical reaction of the complex on targeted DNA site can be governed.<sup>5</sup> Given this, and in view of many other applications, there is a large interest in understanding the binding properties of RLCs, particularly of polypyridyl complexes, to DNA.

Various criteria that can be used to distinguish between the binding modes in solution have been reported.<sup>6,7,8</sup> These criteria derive from changes in the spectroscopic properties of the probe when interacting with DNA, and from structural differences resulting from the three possible binding modes.<sup>9</sup>

Groove binding and electrostatic binding cause subtle changes only in structure, resulting in a more or less unperturbed conformation of DNA. Intercalation, in contrast, induces a substantial change in the structure of DNA.<sup>8</sup> The chromophore is much closer to the DNA base pairs and induces lengthening, stiffening and unwinding of the DNA helix because the probe (or part of the probe) is inserted between the base pairs.<sup>10,11,12</sup> These changes yield in an alteration of the hydrodynamic properties of the DNA for intercalation but not for groove binding and electrostatic binding. Therefore, methods like viscosity, melting studies and CD -spectroscopy that can evaluate the lengthening, stiffening and unwinding of the DNA helix and enable to distinguish between the binding modes.<sup>8</sup> Furthermore, changes in absorption and emission properties allow qualitative and quantitative evaluation of the binding mode of a probe to DNA. Steady state polarization as well as fluorescence energy transfer from DNA bases to the bound probe were used to investigate the binding mode.<sup>7,9</sup>

Factors that influence the binding affinity and selectivity of the chromophores to the DNA are also of interest.

The planarity of the main ligand of an RLC is thought to play a key role in both the binding mode and in affinity.<sup>1</sup> Large and flat aromatic ligands that offer a good overlap with the DNA base pairs display a high affinity to DNA and are good intercalators. In contrast,  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$  (where *bpy* stands for 2,2'-bipyridyl, and *phen* for 1,10-phenanthroline) has a rather poor affinity to DNA. Additionally, ancillary ligands have an effect on the binding of the complex to DNA. An increase in steric hindrance of the ancillary ligand enhances the enantioselectivity of the complex as was found on comparison of  $\text{Ru}(\text{phen})_3$  and  $\text{Ru}(\text{dpp})_3$  (where *dpp* stands for 4,7-diphenylphenanthroline). Thus, the  $\Delta$ -isomer is preferred in binding to right handed DNA.<sup>13,14</sup> Other examples exist in literature where ruthenium complexes have been derivatized and the binding affinity was improved.<sup>15,16</sup>

We report on luminescent ruthenium ligand complexes (RLCs) that have been functionalized in two ways. In the first the main ligand was linked to a quaternary ammonium group. In the second, (2 in Fig 3.1.) the main ligands of two RLCs have been linked by an aliphatic chain that contains two quaternary ammonium groups to improve their binding affinity to DNA. The probes are inert to protonation and substitution. It is noted that dinuclear complexes have attracted less attention in preceding studies.<sup>17,18,19</sup>

Two modes of intercalative binding exist for the dimeric forms beneath electrostatic binding and groove binding. In case of mono-intercalation one subunit is intercalated, while the other is either bound in a groove or is freely dangling. In case of bis-intercalation, both subunits are intercalated, either in the minor or major groove, the bridging chain residing in the opposite groove.<sup>18</sup>

Thus, we have investigated the binding mode of the dinuclear complexes that differ in the length of the aliphatic chain. DNA binding studies have been carried out for the complexes and are compared to the parent RLC  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$ .

## 3.2 Material and methods

### 3.2.1 Chemicals

Common chemicals, solvents, ruthenium(II)-dibipyridyl dichloride [Ru(bpy)<sub>2</sub>Cl<sub>2</sub>] and 5-amino-1,10-phenanthroline, calf thymus (ct) and fish (salmon) sperm (fs) DNA were purchased from Sigma-Aldrich ([www.sigmaaldrich.com](http://www.sigmaaldrich.com)). They were used without further purification. Doubly distilled water was used for preparation of buffers and DNA solutions. The DNA concentration per nucleotide was determined by absorptiometry using a value of 6600 M<sup>-1</sup>cm<sup>-1</sup> for the molar absorbance at 260 nm. All DNA solutions gave ratios of UV absorbance at 260 nm and 280 nm of about 1.9:1, indicating that the DNA was sufficiently free of protein.<sup>20</sup> The probes were first dissolved in 300 μL DMSO. Then water was added until the required endvolume was reached.

### 3.2.2 Buffers

Depending on the pH to be adjusted and on other requirements, we have used (a), a 10 mM Tris buffer [tris(hydroxymethyl)aminomethane] of pH 7; (b) a 10 mM CAPS buffer [3-(cyclohexylamino)-1-propanesulfonate] of pH 11; (c) a BPE buffer (containing 6 mM of Na<sub>2</sub>HPO<sub>4</sub>, 2 mM NaH<sub>2</sub>PO<sub>4</sub> and 1 mM EDTA) of pH 7.

### 3.2.3 Instrumentation

#### Absorption Spectra

Absorption spectra were recorded on a Cary Varian 50 Bio spectrophotometer ([www.varianinc.com](http://www.varianinc.com)). Titrations (probe absorbance vs. DNA concentration) were performed by keeping the concentration of the RLC (**1** or **2a – e**) constant while varying the concentration of the nucleic acid. Absorbance was recorded immediately after addition of the respective DNA solution.

## Melting Studies

These were carried out at 260 nm using a Cary Varian 100 spectrophotometer ([www.varianinc.com](http://www.varianinc.com)) with a temperature controller. Thermal denaturation temperatures of fs-DNA were measured in presence and absence of the RLCs at an RLC-to-DNA ratio of 1:10 both in Tris buffer of pH 7 and the CAPS buffer of pH 11. The temperature of the solution was increased by 2 °C per minute and the absorbance at 260 nm was recorded continuously.

## Fluorescence Data and Binding Constants

Fluorescence spectra were recorded on an Aminco Bowman Series 2 (AB-2) spectrofluorometer. Fluorescence titrations were performed by keeping the concentration of the RLC constant while increasing the concentration of the DNA. Binding constants were calculated from the fluorescence titration data according to the model of McGhee and von Hippel.<sup>21</sup> The fraction of the bound complex was calculated (assuming a linear spectral response) from the relation

$$C_b = C_t \frac{F - F_0}{F_{\max} - F_0} \quad (3.1.)$$

where  $C_t$  is the total concentration of the RLC,  $F$  the observed fluorescence emission at a certain DNA concentration,  $F_0$  the fluorescence intensity in the complete absence of DNA, and  $F_{\max}$  the fluorescence intensity of the complex when completely bound by DNA.<sup>40</sup> Binding data were determined according to Scatchard (with a plot of  $r/C_f$  versus  $r$ , where  $r$  is the binding ratio  $C_b/[DNA]$ , and  $C_f$  is the concentration of the free ligand) and plotted according to the model of McGhee and von Hippel.<sup>21</sup>

Luminescence lifetimes were determined on an ISS K2 ([www.iss.com](http://www.iss.com)) spectrofluorometer using the phase modulation method. Fluorescence was excited with an argon ion laser at 488 nm. The lifetimes of the RLCs were measured either in absence and presence of nucleic acid at a [RLC]/[DNA] ratio of 1:20.

## Measurement of viscosity

Viscosity experiments were performed on a KPG Ubbelohde viscosimeter (www.schottinstruments.com) immersed in a temperature bath thermostated to 25 °C. The kinematic viscosity was calculated according to

$$v = K\left(t - \frac{E}{t^2}\right) \quad (3.2.)$$

where K is an instrumental constant, E the kinetic energy correction factor and t is the flow time of the sample. The inserted flow time was always the average of at least 20 runs. The values of K and E were determined experimentally by measuring the flow time of water at 20 °C and 25 °C. Hence, K was calculated as 0.00983 mm<sup>2</sup>/s<sup>2</sup> and E to 100.7 mm<sup>2</sup>/s from the obtained flow time and the literature values of the viscosity of water at the given temperatures. The dynamic viscosity was calculated from the kinematic viscosity via equation 3.3.:

$$\eta = v / \rho \quad (3.3.)$$

where  $\rho$  is the density of the solution.<sup>22</sup>

Then, the viscosity of a 0.5 mM DNA solution in 10 mM BPE buffer (pH 7) or 10 mM CAPS buffer (pH 11) was determined to obtain  $\eta_0$ . The used DNA solution was first sonicated<sup>23</sup> in order to minimize complications arising from DNA folding.

Furthermore, an appropriate amount of the solution of the probe was added to receive molar ratios of [probe] to [DNA] of 0.4, 0.8 and 1.2. Solutions were mixed by bubbling nitrogen through the solution. The resulting flow times were used to calculate the corresponding viscosity of the solution.

## Polarization Spectra

Fluorescence polarization was measured on a ISS K2 spectrofluorimeter in a L-shaped geometry (www.iss.com). Samples were excited at 460 nm by light from a xenon lamp and the emission was monitored after passing an RG 610 filter from Schott. The orientation of the polarizers was checked with solutions of glycogen. Ten readings were averaged for a single measurement and the standard deviation was usually less than 6 %. The polarization of the

RLCs was measured (a) in absence of DNA, and (b) in presence of DNA in a molar ratio [RLC]:[DNA] of 1:20.

### 3.3 Syntheses

#### 3.3.1 Synthesis of Compounds 3 a-e

2-(Boc-amino)-ethyl bromide and 3-(Boc-amino)-propyl bromide are commercially available but were prepared in our lab as described in section 5.2. To N,N,N',N'- $\alpha,\omega$ -tetramethyl-diamino-alkane, where the alkyl chain can be propyl, butyl or hexyl, a ten fold excess of 2-(Boc-amino)-ethyl bromide or 3-(Boc-amino)-propyl bromide were added and the mixture was stirred over night at room temperature. The resulting paste was washed with ethyl acetate to remove the unreacted Boc-protected amine and form a white precipitate, that was filtrated and dried under vacuum. The white powder was dissolved in water and the solution was refluxed for 12 h, to remove the Boc-protecting group. The water was removed by rotary evaporation and the white residue was dried under vacuum over P<sub>2</sub>O<sub>5</sub> (see section 5.2.6.)

**3a:** n = 2, m = 4

**3b:** n = 3, m = 3

**3c:** n = 3, m = 4

**3d:** n = 2, m = 6

**3e:** n = 3, m = 6

**Figure 3.1.** Chemical structure of the Amines 3 a – e.

### 3.3.2 Synthesis of Probe 1

The RLC  $[\text{Ru}(\text{bpy})_2(\text{ITC-phen})](\text{PF}_6)_2$  (where ITC stands for isothiocyanate) is commercially available but was prepared in our lab according to the literature.<sup>24</sup> A solution of trimethylammonium-ethylamine hydrochloride in methanol was added to a solution of  $[\text{Ru}(\text{bpy})_2(\text{ITC-phen})](\text{PF}_6)_2$  in 1 mL of acetone. Then, 100  $\mu\text{L}$  of triethylamine were added and the solution was stirred for 3 h. The product was purified by column chromatography with a mixture of acetonitrile/water (80:20, vv) as eluent. The third band was collected. After the removal of acetonitrile,  $\text{NH}_4\text{PF}_6$  was added to the remaining aqueous solution to form a red precipitate which was filtered and dried over silica gel. (see section 5.2.7.).

**Figure 3.2.** Synthetic pathway of probe 1.

### 3.3.3 Synthesis of Dinuclear Complexes

A solution of  $[\text{Ru}(\text{bpy})_2(\text{ITC-phen})](\text{PF}_6)_2$  in 3 mL of acetone was added to a solution of the appropriate amine **3 a-e** in methanol. Then, 100  $\mu\text{L}$  of  $\text{NEt}_3$  were added and the solution was stirred for 3 h. A red precipitate was obtained after addition of  $\text{NH}_4\text{PF}_6$ , which was filtered and dried over  $\text{P}_2\text{O}_5$ . The red solid was purified by column chromatography on acidic alumina as stationary phase. The first band was eluted with a mixture of acetonitril/water (vv,

90:10), the second band, containing the product, by using acetonitrile/water (vv, 80:20) as eluent. After the acetonitrile was removed,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate that was filtered and dried. The resulting red powder was resolved in acetone and the product precipitated by the addition of water, filtered and dried under vacuum over KOH. (see section 5.2.8.)

### 3.4 Results and Discussion

*Synthesis.* The strategy for chemical synthesis of the probes is rather straight forward and governed by the need for an affordable and rather short synthetic procedure. Probe **1** is obtained in 56 % yield in a single step from a commercial precursor by reacting it with a large excess of trimethylammoniummethylamine. Addition of excess ammonium hexafluorophosphate favors crystallization of the yellow product. Probes **2a – e** were obtained in a similar way and in one step by reacting two equivalents of the reactive isothiocyanate with a diamine containing the quaternized ammonium groups.

**Figure 3.3.** Synthetic pathway to probes **2a - e**.

<b>2</b>	<b>n</b>	<b>m</b>
<b>a</b>	<b>2</b>	<b>4</b>
<b>b</b>	<b>3</b>	<b>3</b>
<b>c</b>	<b>3</b>	<b>4</b>
<b>d</b>	<b>2</b>	<b>6</b>
<b>e</b>	<b>3</b>	<b>6</b>

### 3.4.1. Absorption Spectra

The probes **1** and **2a - e** have absorption maxima at 454 nm. The molar absorbances ( $\epsilon$  values) at the longwave absorbance maximum are  $15,000 \text{ L mol}^{-1} \text{ cm}^{-1}$  for probe **1** and, as expected, about twice as high ( $30,000 \text{ L mol}^{-1} \text{ cm}^{-1}$ ) for **2a - e**. The bands are attributed to metal-to-ligand charge-transfer (MLCT) transitions. The second peaks (at 285 nm) are attributed to intraligand (IL)  $\pi \rightarrow \pi^*$  transition. Addition of DNA at pH 7 induces a slight hypochromic effect on both absorption bands and results in small red shift (2 nm) of the MLCT and IL band of the mononuclear probe **1**, with an isosbestic point at 475 nm (see Figure 2B). These spectra are similar to those obtained for  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$ , a known semi-intercalator,<sup>11</sup> where the *phen* ligand is partially located between the base pairs of the DNA. On the other hand, the intensities of the MLCT transitions of probes **2a - e** increase on addition of DNA and show an  $\sim 8$  nm longwave shift (Figure 2A). The transition probability of the metal ligand charge transfer is increased as opposed to the mononuclear probe **1**. At a concentration ratio of  $[\text{DNA}]/[\text{Ru}]$  of 1.9:1, the absorbance of the MLCT band decreases. Such behavior was also reported for the two bimetallic ruthenium complexes with bipyridyl ligands, linked, however, by a non-charged aliphatic chain.<sup>25</sup>

A hypochromic effect of  $\sim 40\%$  can be observed (see Figure 2 C,D) for complexes **1** and **2b** at pH 11. This increase in hypochromism that was found for all complexes (**2a - e**) in presence of DNA, is indicative of a better stacking of the dye between the DNA base pairs.

**Figure 3.4.** Visible absorption spectra of probes **1** and **2b** (conc.  $5 \mu\text{M}$ ) in the presence of increasing quantities of ct-DNA in Tris buffer and CAPS buffer after subtraction of the intrinsic absorbance of DNA; (A) Titration of **2b** with ct-DNA at pH 7. (B) Titration of **1** at pH 7; (C) Titration of **2b** at pH 11; (D) Titration of **1** at pH 11. The arrows show spectral changes upon increasing DNA concentration.

### 3.4.2 Luminescence Titration

Probes **1** and **2a – e** emit moderately strong luminescence (with a QY of  $\sim 0.02$ - $0.05$ ) in the absence of DNA in buffered solution, with a peak at 605 nm. This is characteristic of the  $^3\text{MLCT}$  emission state. The probes, in constant concentrations, were titrated with ct- and fs-

DNA in Tris buffer of pH 7 and in CAPS buffer of pH 11. The results are shown in Figure 3. Like in the case of the absorption spectra, changes in emission occur immediately after addition of DNA which is evidence for a very fast ( $< 1$  s) binding process. The emission intensities of probes **1** and of the parent compound  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$  do not substantially vary with the DNA concentration at pH 7. The intensities of the dinuclear complexes **2a** – **e** decrease slightly but significantly at neutral pH. Similar plots were reported in cases of ruthenium complexes<sup>26,27,28,29</sup> and organic dyes.<sup>30,31</sup>

The weak quenching effect is said to result from an electron transfer from the guanine bases of DNA to the  $^3\text{MLCT}$  state of the RLC, and/or from the formation of a photo-adduct between RLC and DNA.

**Figure 3.5.** Luminescence titration of  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$  ( $\blacklozenge$ ), **1** ( $\blacktriangle$ ) and **2b** ( $\blacktriangledown$ ) in Tris buffer of pH 7 and  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$  ( $\blacktriangleright$ ), **1** ( $\bullet$ ) and **2b** ( $\blacksquare$ ) in CAPS buffer of pH 11 upon addition of increasing quantities of DNA. The [RLC] was kept constant at 1  $\mu\text{M}$ .

The situation is quite different at pH 11. On addition of DNA, the dimeric probes **2a** – **e** undergo a 4-fold increase in emission intensities. A larger increase is also found for probe **1** compared to the results obtained for pH 7. This suggests that all RLCs interact more strongly with DNA at basic pHs, possibly a result of a structural change of the DNA. It was found that the denaturation of calf thymus DNA at pH  $\sim 11$  proceeds by initial guanine deprotonation followed by thymine deprotonation. This is combined with a decrease in base stacking.

Although these two changes in base protonation are coupled to a change in conformation, the B-conformation does not totally disappear.<sup>32</sup>

The data of the emission titration data at pH 11 was used to determine binding constants via a Scatchard plot (eq. 3.4.),<sup>33</sup> where  $r$  is the ratio of bound complex to DNA concentration, and  $c_f$  is the concentration of the unbound RLC. The data were fitted by nonlinear least-squares analysis according to the McGhee and von Hippel equation governing random noncooperative binding to a lattice.<sup>21</sup>

$$\frac{r}{c_f} = K_b \frac{(1-nr)^n}{[1-(n-1)r]^{n-1}} \quad (3.4.)$$

where  $K_b$  is the binding constant and  $n$  the size of the binding site. The best fit is reached after variation of the two parameters: the binding constant  $K_b$  and the size binding site  $n$ , which measures the degree of anticooperativity, averaged over all possible sequences on the helix. The values obtained are summarized in Table 1. As can be seen, the binding constants are in the range of  $10^7 \text{ M}^{-1}$ , independently of the DNA used, and comparable to the binding constant of ethidium bromide.

**Figure 3.6.** Scatchard plot of **2b** with fs-DNA in 10 mM CAPS buffer pH 11.

**Table 3.1.**  $K_b$  values of ct and fs-DNA; and  $\Delta T_m$  values of fs-DNA as obtained with different probes

Probe	$K_b$		$\frac{[DNA]}{[RLS]}$	$\Delta T_m / ^\circ C$		Ref.

<b>2e</b>	$1.06 \times 10^7$	$1.45 \times 10^7$	10	16.7	17.7	this work
EtBr	$1.0 \times 10^7$		10	13		[41]
$\Delta$ - $[Ru(phen)_2(dppz)]^{2+}$	$3.2 \times 10^6$		1	16		[2]
$\Lambda$ - $[Ru(phen)_2(dppz)]^{2+}$	$1.7 \times 10^6$		1	5		[2]

<sup>a</sup> Changes in luminescence were too small to allow for unambiguous determinations.

It was not possible to determine binding constants for  $[Ru(bpy)_2(phen)]^{2+}$  via luminescence titrations because no saturation is reached and therefore the intensity of the fully bound complex could not be determined. The literature gives a binding constant for the  $[Ru(bpy)_2(phen)]^{2+}$ /DNA system of  $0.84 \times 10^4 \text{ M}^{-1} (\text{bp}^{-1})$ .<sup>15</sup> Hence, binding of probes **1** and **2a** – **e** to DNA is much stronger and comparable to the binding constant observed for  $[Ru(phen)_2(dppz)]^{2+}$  ( $10^6 \text{ M}^{-1}$ ) which binds intercalatively.<sup>2</sup>

### 3.4.4 Thermal Denaturation

Further evidence for intercalation of the RLCs into the DNA helices was obtained from studies on the melting temperature of the DNAs. Intercalation of small molecules into their double helix is known to increase the DNA melting temperature, i.e. the temperature at which 50 % of the DNA has become single stranded.<sup>34,35</sup> The molar absorbance of DNA bases at 260 nm is much smaller in the double helical form than in the single-stranded form. Hence, melting of the helix leads to an increase in the absorption at this wavelength. Thus, the helix-to-coil transition can be determined by monitoring the absorbance of the DNA at 260 nm as a

function of temperature.

As shown in Figure 3.7, in the absence of complex, the temperature of melting ( $T_m$ ) of fs-DNA is 68.2 °C in 10 mM Tris buffer and 61 °C in 10 mM CAPS buffer. The  $T_m$  of pure fs-DNA was found to increase at both pHs at an [RLC]:[DNA] of 1:10.  $T_m$  was increased by 8.8 °C in the case of probe **1** and by ~15 °C in the case of the dinuclear probes **2a** – **e** at pH 7 as shown in Figure 3.7. While probe **1** causes an increase in  $\Delta T_m$  similar to the one of the parent compound  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$ , the dimeric forms **2a** – **e** cause  $\Delta T_m$  values that are comparable to some common DNA intercalators (Table 1). The thermal denaturation study at pH 11 results in a similar increase of  $T_m$ . These data are also presented in Table 3.1. The largely increased  $\Delta T_m$ , at both pH 7 and pH 11 suggests an intercalative binding mode.<sup>8, 34, 35</sup>

**Figure 3.7.** Thermal denaturation curves of fs-DNA (■) (100 μM) at pH 7 (TRIS buffer) at a concentration ratio of [DNA] to [RLC] of 10 with probes **1** (●) and **2b** (▲).

### 3.4.5 Polarization of the Emission

Electrostatic binding does not substantially restrict the rotational freedom of a DNA-bound RLC whereas intercalative binding fixes the intercalator in a specific orientation and therefore severely restricts certain modes of rotation. The predicted restriction in the rotation of an intercalated dye can be experimentally verified by measurement of the polarization of the emission

Therefore, intercalative binding, in contrast to the surface-bound mode, is expected to result in more distinctly polarized emission. Consequently, steady-state polarization can be used as a parameter that indicates the extent of intercalative binding. Steady state polarization

(P) is defined as

$$P = \frac{I_{//} - I_{\perp}}{I_{//} + I_{\perp}} \quad (5)$$

where  $I_{//}$  and  $I_{\perp}$  are the emission intensities at parallel and perpendicular directions, respectively, to the plane of the excitation light.<sup>36</sup> The steady state polarization was measured for the probes **1** and **2a – e**, and for the parent compound  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$  at a concentration ratio of [RLC]:[DNA] of 1:20 in buffers of pH 7 and 11, respectively. The results are summarized in Table 2 and reveal that all probes show significant polarization for excitation at the MLCT band. The polarization of the RLCs is nearly zero in absence of DNA and at various of pH values.

**Table 3.2.** Luminescence polarization and decay times of probes **1** and **2a – e**

Probe	Polarization <sup>a</sup>				$\tau$ (ns)

<sup>a</sup> Polarization was measured at a concentration ratio of [DNA]:[RLC] = 20:1

<sup>b</sup> free probe

<sup>c</sup> shorter lifetime ( $\tau_{\text{short}}$ ) and longer lifetime ( $\tau_{\text{long}}$ ) component of the bound complex, [DNA]:[RLC] = 20:1, numbers in parentheses are the weighing factors of the lifetime components.

However, polarization is increased on addition of DNA at both pHs. Figure 3.8 shows

the increase of the relative polarization of  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$ , and of probes **1** and **2b** (all at 10 mM concentration) with increasing concentrations DNA. The mononuclear probe **1** shows distinctly higher polarization compared to  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$ . Furthermore,  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$ , unlike **1** and **2a – e**, reaches no saturation. Probe **1**, in contrast, reaches maximal polarization at a [DNA]:[RLC] concentration ratio of 20:1 which is similar to the situation with dinuclear RLCs.

Not unexpectedly, the enhancement in polarization for the dinuclear probe **2c** is larger than for **1** and for  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$  as can be seen in Figure 3.8 and Table 3.2. This clearly indicates a more efficient rigidization of the dinuclear complex through their binding to DNA compared to the mononuclear complexes. These results again indicate that all RLCs investigated bind in an intercalative mode.

**Figure 3.8.** Emission polarization of  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$  (■), **1** (▲) and **2c** (●) in the presence of fs-DNA in 10 mM CAPS buffer of pH 11. For all measurements  $c(\text{Ru}) = 10 \mu\text{M}$ .

### 3.4.6 Fluorescence Lifetime Studies

The increase in emission intensity of probes **1** and **2a – e** on addition of either fs- and ct-DNA is associated to an increase in decay time. Previous studies have revealed that luminescence decay in the presence of DNA is best described by a bi-exponential fit.<sup>29,37</sup> The longer lifetime component of the biexponential decay is associated with the intercalated, groove-bound probe adduct. The shorter lifetime component, having an emission lifetime

characteristic for the free RLC, is related to the surface-bound probe.<sup>38</sup>

Intercalative binding reduces the mobility of the intercalator, as shown by polarization data, and also can significantly increase the excited-state lifetime. Hence one would expect to see a longer-lived component for the intercalated RLC than for free RLCs. Moreover, due to the similarity in the spectroscopic data of **1** and **2a – e** compared to other RLCs where this long-lived component was found to correspond to the emission of the intercalative bound species<sup>14</sup> we assume that probes **1**, **2a - e** bind in similar fashion.

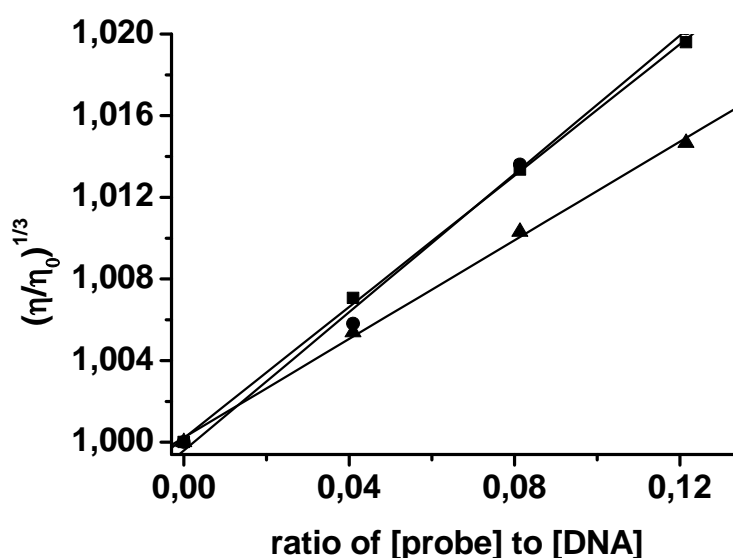

Excited state lifetimes were determined by the phase modulation technique, using a 488 nm argon ion laser, in absence and presence of fs-DNA at a [RLC]:[DNA] concentration ratio of 1:20 at pHs of 7 and 11. Data are listed in Table 3.2. All RLC probes display single exponential decays of typical 400 – 600  $\mu$ s in the absence of DNA<sup>39,1</sup> In presence of DNA, the decays of  $[\text{Ru}(\text{bpy})_2(\text{phen})]^{2+}$  and probe **1** remain mono-exponential, whilst the dinuclear complexes decay biexponentially. The biexponential fit results in a short-lived component ( $\sim$  400  $\mu$ s) and a longer lived component ( $\sim$  900  $\mu$ s). The shorter lifetime components correspond well to the lifetimes in absence of DNA. Therefore, the shorter lived emission is assigned to the surface bound RLC. These results strongly support the assumption that the dinuclear RLCs bind to DNA in two modes: intercalation and surface binding.

### 3.4.7 Viscosity Studies

Photophysical probes can provide necessary, but not sufficient clues to support a binding model. Hydrodynamic parameters like viscosity are known to be sensitive to changes in the length of a macromolecule like DNA and are regarded as the least ambiguous and most critical test of a binding model in solution, particularly if crystallographic structural data cannot be acquired. A classical intercalation model results in lengthening of the DNA helix because base pairs are more separated in the probe/DNA aggregate so to accommodate the probe, this leading to an increase in the viscosity of the solution. Nonclassical intercalation (including groove binding) of a probe, in contrast, causes a bending of the helix, reduces its effective length, and consequently reduces viscosity. As a result, groove binding typically causes no change in viscosity.<sup>40,8</sup>

Figure 3.9. shows the effect of the new DNA probes **1** and **2a**, along with that of ethidium bromide, on the viscosity [plotted as  $(\eta/\eta_0)^{1/3}$ ] of rod-like fs-DNA as a function of

the [probe]:[DNA] ratio. Here,  $\eta$  and  $\eta_0$ , respectively, are the viscosities in presence and absence of the probe. They are proportional to  $L/L_0$  [where  $L$  is the length of the rodlike DNA in presence ( $L$ ) and absence ( $L_0$ ) of the probe]. Ethidium bromide increases the viscosity by lengthening the DNA helix. Viscosity is also enhanced on adding increasing quantities of probes **1** and **2a**. The same effect on viscosity is observed when the experiment is performed in buffer of pH 11. The results again support the previous conclusion (made from spectral analysis) that intercalation is the overwhelmingly dominant mechanism of interaction.

**Figure 3.9.** Relative viscosity of fs-DNA (0.5 mM) upon addition of ethidium bromide (▲), **1** (●) and **2a** (■) in BPE buffer of pH 7

### 3.5 Conclusions

Binding constants in the order of  $10^7 \text{ M}^{-1}$ , the hypochromicity of the absorption bands, and a significant enhancement of luminescence in the presence of DNA indicate strong and intercalative binding of probes **1** and **2a – e** with double-stranded DNA. Further support is provided by the increase in polarization and lifetime of their luminescence. Given this and the fact that all probes increase the melting temperature of DNA and enhance the viscosity of its solutions, it is concluded that the probes bind intercalatively to DNA. The results are essentially the same at pH 7 and pH 11 and virtually independent of the type of buffer, even

though the absorption spectra and luminescence measurements show a slight dependency on pH. Probes **1** and **2a – e** comply with the expectation that they interact with ct-DNA and fs-DNA with the same affinity.

The hyperchromicity of absorption and the decrease in luminescence intensity of the probes **2a-e** in the presence of DNA at pH 7 correlates well to the spectral properties of other RLCs like [Ru(TAP)<sub>3</sub>] and [Ru(bpy)(hat)<sub>2</sub>].<sup>29,26</sup> At pH 11 RLCs **2a-e** show an 4-fold increase in luminescence intensity on addition of DNA, whereas probe **1** shows only an 2 fold increase. The dinuclear ruthenium probes **2a – e** display higher polarization on addition of DNA as probe **1** and their template [Ru(bpy)(phen)]<sup>2+</sup>. This along with the resulting higher melting temperatures and the increase in viscosity of the DNA in presence of probe **2a-e** indicates a stronger binding to DNA compared to the probes studied. However, the length of the linking chain of the dinuclear complexes does not affect any binding properties to DNA. There is a 4-fold increase in emission intensity on addition of DNA for all probes (**2a-e**). The enhancement of polarization and lifetime in presence of DNA and the increase of DNA melting temperature ( $\Delta T_m \approx 15$  °C) are similar for each dinuclear probe. In fact, probes **2a – e** are almost equivalent in terms of probing DNA.

# 4. Determination of DNA via Resonance Light Scattering Technique with New Ruthenium Derived Probes

## 4.1 Introduction

Nucleic acids play a significant role in life processes, thus research on them has become an essential part in life sciences. Various analytical methods have been developed for mutation detection, elucidation of complex biological problems, molecular diagnosis and prognosis of diseases and quantitative determination.<sup>1</sup> Luminescence based methods have found wide application in the development of these methods. Therefore, a number of luminescent probes have been developed including organic dyes such as ethidium bromide,<sup>2,3,4,5</sup> diaminophenylindole (DAPI),<sup>6,7,8</sup> bisimidazole (Hoechst 33258)<sup>9,10,11</sup> and thiazole orange homodimers (TOTO),<sup>12,13</sup> metal complexes and metal ions,<sup>14,15</sup> especially the lanthanide (III) cations.<sup>16,17</sup> In 1993, Pasternack et al. proposed the resonance light scattering technique to determine biological macromolecules.<sup>18,19</sup> It became one of the most important methods for determination of DNA and proteins.

In common spectrofluorometry, light scattering is a major source of interference that should be minimized. The resonance light scattering (RLS) technique, in contrast, takes advantage of this effect.<sup>29</sup> The RLS signals, which can easily be obtained by simultaneously scanning, the excitation and emission monochromators of a common spectrofluorimeter with  $\Delta\lambda = 0$  nm, have been applied to determine biological macromolecules like DNA,<sup>20,21,22</sup> proteins<sup>23,24,25</sup>, trace amounts of inorganic ions<sup>26</sup>, and cationic surfactants.<sup>27,28</sup> Sensitivity of this method is at the nanomolar level. Some RLS methods for DNA have limits of detection of  $< 1$  ng mL<sup>-1</sup> and are hence more sensitive for DNA detection than fluorescence methods using ethidium bromide.<sup>29,30</sup> Therefore, RLS combines sensitivity with the benefits of simplicity and versatility.

Polypyridyl ruthenium (II) complexes are useful in DNA research due to the fact that they show many interesting effects while bound to DNA.<sup>31,39</sup> Luminescent ruthenium complexes have been used as sensitive probes for DNA,<sup>32,33,34</sup> DNA hybridization<sup>35,36</sup> and DNA-drug interactions.<sup>37</sup> Furthermore, some of them are able to distinguish between B- and Z-DNA,<sup>38</sup> others act as light switches for DNA<sup>39</sup> or can be used in single mismatch

detection.<sup>40,41,42</sup> Here we present an RLS method for a DNA assay under neutral pH conditions using probe **2b** (see Figure 1). Due to the positive charges on its molecular structure, probe **2b** can bind to the DNA polyanion through electrostatic interactions. Based on this adsorption and aggregation, the RLS signals are largely enhanced.

Compared to previous RLS methods, the method presented here offers low detection limits and a wide linear range. Most importantly, measurements can be performed under neutral pH conditions and do not require further additives like SDS or CTMAB.

## 4.2 Materials and Methods

### 4.2.1 Chemicals

Common chemicals, solvents, [Ru(bpy)<sub>2</sub>Cl<sub>2</sub>], calf thymus (ct) and salmon sperm (fs) DNA were purchased from Sigma-Aldrich ([www.sigmaaldrich.com](http://www.sigmaaldrich.com)). All chemicals were used without further purification. The RLCs were synthesized according to chapter 5.2.. Doubly distilled water was used for preparation of buffers, probe and DNA solutions. A 12 mM Britton-Robinson (BR) buffer was used in all RLS experiments. The DNA concentration per nucleotide was determined by absorption spectroscopy using 50 μg mL<sup>-1</sup> per optical density for the molar absorption at 260 nm. All DNA solutions gave ratios of UV absorbance at 260 nm and 280 nm of about 1.9:1, indicating that the DNA was sufficiently free of protein. Stock solutions of the probes of a concentration of 1 x 10<sup>-5</sup> mol L<sup>-1</sup> were prepared by dissolving them first in 300 μL DMSO and then water was added to reach the chosen endvolume.

### 4.2.2 Apparatus

An Aminco Bowman Series 2 (AB-2) spectrofluorimeter was used to record the RLS spectra. The absorption spectra were recorded on a Varian 50 Bio photometer ([www.varian.com](http://www.varian.com)). The pH was measured with at a pH meter, type CG 842 from Schott ([www.schottinstruments.com](http://www.schottinstruments.com)).

### 4.2.3 General Procedure

First, 100  $\mu\text{L}$  of the stock solution of the probe and then an appropriate volume of DNA solution were added to the Britton-Robison buffer pH 7, resulting in a total volume of 1 mL. The RLS spectra of the solutions were recorded in 1 cm quartz cuvettes 10 min after mixing. The RLS spectra were obtained by scanning synchronously the excitation and emission wavelength with  $\Delta\lambda = 0$  nm over the 300 to 600 nm range. The RLS intensities were determined at 468 nm for probe **2a-e** and at 356 nm for probe **1**.

### 4.2.4 Standard Operational Protocol for Determination of DNA

Each sample was prepared in the following order: BR buffer (pH 7), 0.1  $\mu\text{L}$  of probe **2b** ( $1 \times 10^{-5}$  mol  $\text{L}^{-1}$ ) and an appropriate volume of DNA solution. The total volume of each sample was 1 mL. The RLS intensity at 468 nm was recorded after an incubation time of 10 min. For the calibration curve  $I/I_0$  was plotted versus the DNA concentration, where  $I$  was the  $I_{\text{RLS}}$  of the investigated sample and  $I_0$  the RLS intensity of the respective probe in absence of DNA. The measured  $I_{\text{RLS}}$  intensity of a sample, containing an unknown amount of DNA, was fitted with a linear regression of the calibration curve to determine the DNA concentration.

**Figure 4.1.** Chemical structure of probe **1**, **2a-e**

## 4.3 Results

### 4.3.1 Features of RLS Spectra

The RLS spectra of probe **2b**, DNA and a mixture of **2b** and fs-DNA are shown in Fig 4.2. The RLS signals of probe **2b** and DNA alone are very weak over the total region scanned. However, their mixture shows very high RLS signals indicating that an interaction between DNA and probe **2b** has occurred. It was found that the increase in RLS signal is directly proportional to the DNA concentration and can be used for DNA determination. Among the three RLS peaks of 356 nm, 398 nm and 468 nm, the peak at 468 nm was selected for DNA determination with all dinuclear complexes (**2a-e**), except for the mononuclear probe **1** which shows the highest RLS signal at 356 nm.

Pasternack et al. proposed that a RLS effect is observed as increased scattering intensity near or within the absorption of an aggregated molecular species.<sup>19</sup> The extent to which a particle absorbs and scatters light depends on its size, shape and refractive index  $m$  to the surrounding solution. If the wavelength of the incident light is close to an absorption band,  $m$  increases enormously. Enhanced light scattering takes place due to the fact the scattering cross section is a much stronger function of  $m$  than the absorption cross section (see equation 2.1.).<sup>43</sup> The maximum RLS peak at 468 nm is near the metal ligand charge transfer (MLCT) absorption band of **2b** at 454 nm (Fig 4.3.) according to the theory of Pasternack et al.<sup>19</sup>

As shown in Fig 4.3., in presence of DNA the absorption of probe **2b** at 280 nm is reduced and a slight red shift of both absorption bands is observed. These effects are proof for the aggregation between **2b** and DNA. Aggregation is the second enhancement factor for RLS signals. The absorption of a solution with a fixed concentration of the aggregating component remains unperturbed, whereas the amount of scattering depends on the square of the volume of the aggregate. Thus, RLS enhancement is a result of aggregation. Therefore, RLS is extremely sensitive to even low concentrations of extended aggregates.<sup>18</sup>

**Figure 4.2.** RLS spectra of (a) **2b** ( $1 \times 10^{-6}$  mol L<sup>-1</sup>), (b) DNA ( $1.5 \mu\text{g mL}^{-1}$ ), (c) **2b** +  $0.8 \mu\text{g mL}^{-1}$  fs-DNA, (d) **2b** +  $1.5 \mu\text{g mL}^{-1}$  fs-DNA. Buffer, pH 7.

**Figure 4.3.** Absorbance spectra of **2b** in presence (●) and absence (▲) of fs-DNA. **2b**: 10  $\mu\text{M}$ , DNA:  $3 \times 10^{-4} \text{ mol L}^{-1}$ , 10 mM TRIS pH 7.

### 4.3.2 Effect of pH

The effect of pH on the RLS intensity was investigated over a pH range of 2 - 11 for probes **1**, **2a-e**. pH has a strong influence on the RLS signal of DNA-probe complex. The RLS signals of blank DNA and the probes **1**, **2a-e** in absence of the DNA are very weak and more or less unaffected by pH (Fig 4.4.). The RLS intensities for probes **1** and **2a** in presence of fs-DNA reach their maxima at pH 3.  $I_{\text{RLS}}$  of the probe **2b**-fsDNA aggregate has its maximum at pH 7 (Fig 4.4.), whereas the other dinuclear complexes **2c-e** exhibit their maximum value under slightly basic conditions (pH 8 - 9). Hence, probe **2b** was chosen for further investigation.

**Figure 4.4.** Effect of pH on the RLS signal; (a) **2b**, (b) fs-DNA, (c) **2b** + fs-DNA; **2b**: 1  $\mu\text{M}$ , fs-DNA: 1.5  $\mu\text{g mL}^{-1}$ .

### 4.3.3 Effect of Probe Concentration

The effect of the concentration of **2b** on the RLS intensity is shown in Fig 4.5., where  $I$  is the signal of the **2b**-DNA aggregate and  $I_0$  is the RLS signal of the blank probe **2b**. The concentration of probe **2b** obviously has an effect on the RLS signal on the **2b**-DNA system. It was found that the RLS signal reaches its maximum at a concentration of  $1 \times 10^{-6}$  M of **2b**.  $I_{\text{RLS}}$  decreases at higher concentrations. Therefore, in all experiments a probe concentration of **2b** of  $1 \times 10^{-6}$  mol L<sup>-1</sup> was used.

**Figure 4.5.** Effect of the concentration of probe **2b** on the RLS intensity. DNA: 1.5  $\mu\text{g mL}^{-1}$ , pH 7.  $I_0$  is the signal of the probe in absence of DNA.

### 4.3.4 Effect of Ionic Strength

Effect of ionic strength on the RLS signal was investigated and is shown in Fig 4.6. NaCl was used to adjust the ionic strength of the solution. At low ionic strength, the RLS intensity of the **2b**-DNA complex remains relatively stable. With increasing NaCl concentration the RLS signal decreases distinctly. The sodium ion as a counter ion to the negatively charged DNA molecule shields the negative phosphate groups of the backbone and therefore hinders the interaction between **2b** and DNA. Thus, the RLS signal of the mixture of **2b** and DNA is reduced. The RLS intensities of blank DNA and blank probe **2b** remain unaffected by the ionic strength (data not shown).

**Figure 4.6.** Effect of ionic strength on the RLS signal. **2b**:  $1\mu\text{M}$ , fs-DNA:  $1.5\mu\text{g mL}^{-1}$ , pH 7

### 4.3.5 Effect of Reaction Time

The reaction kinetics were studied by recording RLS intensity every minute within 30 min (Fig 4.7.). The experiment shows that the RLS intensity of the system **2b**-DNA reaches a constant value after 10 min and remains stable for 2 hours (data not shown). Hence, all measurements were performed 10 min after buffer, **2b** and DNA were mixed together. However exact timing is not crucial because of the relatively long stability of the RLS signal.

**Figure 4.7.** Effect of reaction time. **2b**:  $1\mu\text{M}$ , DNA:  $1.5\ \mu\text{g mL}^{-1}$ , pH 7.

#### 4.3.6 Effect of the Order of the Addition of Reagents

Three possible addition orders of the reagents were investigated. Although the addition order weakly influences the RLS intensity, the optimal sequence is buffer, **2b** and DNA, as can be observed from Table 4.1.

**Table 4.1.** Effect of the reagent addition order on the RLS signal ( $I_{\text{RLS}}$ ).<sup>a</sup>

Addition order of reagents	$I_{\text{RLS}}$
Buffer, <b>2b</b> , fs-DNA	6.08
Buffer, fs-DNA, <b>2b</b>	5.45
<b>2b</b> , fs-DNA, buffer	5.41

<sup>a</sup> pH 7; Concentrations: **2b**,  $1 \times 10^{-6}\ \text{mol L}^{-1}$ ; fs-DNA,  $1.5\ \mu\text{g mL}^{-1}$

#### 4.3.7 Effect of Potential Interferents

The effect of proteins, bases, various metal ions and other biochemical reagents on the RLS signals was tested. The results are presented in Table 4.2. The bases, BSA and other biochemical reagents do not interfere at concentrations of  $5\ \mu\text{mol L}^{-1}$ . Most metal ions and phosphate are tolerable up to  $1000\ \mu\text{mol L}^{-1}$ .

**Table 4.2.** Effect of interfering substances on the RLS intensity of the system **2b**-DNA<sup>a</sup>

Substances	Concentration ( $\mu\text{mol L}^{-1}$ )	Change of $I_{\text{RLS}}$ (%)
$\text{Na}^+$	1000	2
$\text{K}^+$	1000	6.2
$\text{Ca}^{2+}$	1000	1.6
$\text{Mg}^{2+}$	1000	2.4
$\text{HPO}_4^{2-}/\text{H}_2\text{PO}_4^-$	1000	3
$\text{Zn}^{2+}$	10	11.6
EDTA	10	9

Glucose	5	3.7
BSA	5 <sup>b</sup>	8.4
Thymine	10	-8.2
Cytosine	5	-6.8
Uracil	5	-12

<sup>a</sup> pH 7; Concentrations: **2b**,  $1 \times 10^{-6} \text{ mol L}^{-1}$ ; fs-DNA,  $1.5 \mu\text{g mL}^{-1}$ .

<sup>b</sup>  $\mu\text{g mL}^{-1}$

### 4.3.8 Calibration Plot

The dependence of the RLS signal on the concentration of nucleic acid was determined under optimum conditions. The analytical parameters of the assay are listed in Table 4.3. It can be seen that the method offers a wide linear range, high sensitivity and good linear correlation. The limit of detection (LOD) is calculated from  $3\sigma/s$ , where  $\sigma$  is the standard deviation of the blank ( $n = 5$ ) and  $s$  is the slope of the linear plot. Each RLS signal is the average of 5 measurements (Fig. 4.8.), where  $I$  is the signal of the **2b**-DNA complex and  $I_0$  is the RLS signal of the blank probe **2b**.

**Figure 4.8.** Calibration graph for the determination of fs-DNA within the concentration range: 0 - 1.8  $\mu\text{g mL}^{-1}$ . **2b:**  $1 \times 10^{-6} \text{ mol L}^{-1}$ ; pH 7.

**Table 4.3.** Analytical parameters for determination of ct- and fs-DNA

DNA	Linear range ( $\text{ng mL}^{-1}$ )	Linear regression equation ( $c: \mu\text{g mL}^{-1}$ )	Correlation coefficient	LOD ( $\text{ng mL}^{-1}$ )
fs-DNA	30 - 1800	$I_{\text{RLS}} = -0.84 + 101.4c$	0.9996	1.6
ct-DNA	30- 1800	$I_{\text{RLS}} = -0.80 + 88.2c$	0.9991	2.7

#### 4.3.9 Determination of DNA in Synthetic Samples

To proof the reliability und adaptability of the method, three synthetic samples were prepared containing three of the investigated interferences, respectively, and a known amount of DNA. The composition of each solution is listed in table 4.4.. According to the linear equations listed in table 4.3. the contents of ct- and fs-DNA in each synthetic sample was determined. The results of the synthetic samples in terms of the DNA content, calculated via the given linear equation (table 4.3.) correspond well with the expected concentration value of DNA. Thus, the determination by this method is reliable, precise and simple.

**Table 4.4.** Results of analysis of synthetic samples

DNA in sample ( $\mu\text{g mL}^{-1}$ )		Additives <sup>a</sup>	DNA found ( $\mu\text{g mL}^{-1}$ )	$\sigma$ (%)
ct-DNA	1	Uracil <sup>b</sup> , EDTA, $\text{K}^+$	1,01	2.1
ct-DNA	1	Glucose <sup>b</sup> , $\text{Mg}^{2+}$ , SDS	0.94	8
ct-DNA	1	BSA <sup>b</sup> , $\text{Zn}^{2+}$ , $\text{PO}_4^{3-}$	1.09	8.2
fs-DNA	1	Uracil, EDTA, $\text{K}^+$	1.05	4.6
fs-DNA	1	Glucose, $\text{Mg}^{2+}$ , SDS	0.95	6.2
fs-DNA	1	BSA, $\text{Zn}^{2+}$ , $\text{PO}_4^{3-}$	1.05	5.4

<sup>a</sup> pH 7; Concentrations of additives for fs-DNA: Uracil:  $5 \times 10^{-6} \text{ mol L}^{-1}$ ; BSA:  $5 \mu\text{g mL}^{-1}$ ; EDTA:  $10 \times 10^{-6} \text{ mol L}^{-1}$ ; SDS:  $10 \times 10^{-6} \text{ mol L}^{-1}$ ; Glucose:  $5 \times 10^{-6} \text{ mol L}^{-1}$ ;  $\text{K}^+$ :  $1 \times 10^{-3} \text{ mol L}^{-1}$ ;  $\text{Mg}^{2+}$ :  $1 \times 10^{-3} \text{ mol L}^{-1}$ ;  $\text{Zn}^{2+}$ :  $1 \times 10^{-3} \text{ mol L}^{-1}$ ;  $\text{PO}_4^{3-}$ :  $1 \times 10^{-3} \text{ mol L}^{-1}$ ; **2b**:  $1 \times 10^{-6} \text{ mol L}^{-1}$ .

<sup>b</sup> pH 7; Concentrations of additives: Uracil:  $10 \times 10^{-6} \text{ mol L}^{-1}$ ; BSA:  $10 \mu\text{g mL}^{-1}$ ; Glucose:  $10 \times 10^{-6} \text{ mol L}^{-1}$ ;

#### 4.3.10 Comparison to Other Methods

The RLS method presented here was compared to other RLS and fluorometric methods (table 4.5.). The organic probes commonly used in fluorometric assays in most cases are very expensive and toxic. Ethidium bromide is well known for its high carcinogenicity.

Furthermore, organic fluorophores only show small Stokes' shifts so that the separation of the excitation and emission light is difficult. This is contrary to RLS measurements, where the excitation and emission wavelength are scanned synchronously. Fluorometric methods also suffer from high background fluorescence, caused by free dye and also from the biological matter. The background signal in RLS technique is very low for both instead.

The presented RLS method features several advantages compared to the methods reported in literature. Its sensitivity is as good as reported for other assays and it can be performed at neutral pH. Only a few RLS methods reported can be done at pH 7 (see Table 4.5.) and without surfactants, which increase the background RLS signal of both blank dye and DNA. In summary, the method is highly sensitive, can be performed at neutral pH and

does not require any further surfactants like sodium dodecylsulfonate (SDS) or cetyltrimethylammonium bromide (CTMAB).

**Table 4.5.** Comparison of the presented method to other methods

Probe	Nucleic acid	pH/additive	LOD (ng/mL)	method	Ref.
Ethidium bromide	ctDNA	pH 7.5	10	fluorescence	[44]

<b>2b</b>	ctDNA/fsDNA	pH 7	2.7/1.6	RLS	this work

## 4.4 Conclusion

A new assay was established for quantitative determination of DNA via RLS enhancement. A 200-fold increase in signal intensity of probe **2b** is observed in presence of DNA at pH 7. The RLS signal remains stable for several hours. The assay is highly sensitive and has a wide linear range. Furthermore, fs- and ct-DNA were determined satisfactorily in the presence of potentially interfering substances.

To our knowledge only three other RLS based assays do exist in the literature that are based on ruthenium complexes as probes. The complexes applied in the assays presented in ref. [20] and [56], require acidic conditions. The optimal pH value for the method using  $[\text{Ru}(\text{phen})_2(\text{dppz})]^{2+}$  is 9, with SDS as required as the co-reagent.<sup>57</sup> In contrast to most RLS-based assays, the decrease of RLS signal with increasing amount of DNA is measured.

The method presented here does not require surfactants and can be performed under neutral pH conditions. Moreover, the low LODs of this assay ( $1.6 \text{ ng mL}^{-1}$  for fs-DNA and 2.7 for ct-DNA) are obtained in a very simple way and are definitely comparable to other RLS based methods, but also to well established fluorometric methods. Hence, the RLS assay represents a valuable tool for DNA determination.

## 5. Experimental Part

### 5.1 Material and Methods

#### 5.1.1 Chemicals, Solvents and DNA

All chemicals and solvents used were purchased from Sigma Aldrich ([www.sigmaaldrich.com](http://www.sigmaaldrich.com)) or Acros Organics ([www.acros.be](http://www.acros.be)). All chemicals were of analytical grade and were used without further purification. Buffers and DNA solutions were prepared with doubly distilled water. Tris(hydroxymethyl)-aminomethane buffer (TRIS) of pH 7, 10 mM: 121 mg of TRIS were dissolved in 100 mL of doubly distilled water. 3-(Cyclohexylamino)-1-propanesulfonic acid buffer (CAPS) of pH 11, 10 mM: 221 mg of 3-(Cyclohexylamino)-1-propanesulfonic acid were dissolved in 100 mL doubly distilled water. Britton Robinson buffer (BR) of pH values ranging from pH 2 to pH 11, 120 mM: 228  $\mu$ L acetic acid, 229  $\mu$ L phosphoric acid and 247 mg of boronic acid were dissolved in 100 mL doubly distilled water. The buffers were adjusted to the corresponding pH value with 1 N HCl or 1 N NaOH, respectively. The pH measurements were performed with a Schott pH meter with temperature compensation.

The DNA was obtained as its sodium salt from Sigma-Aldrich. Two different types of DNA were used, once DNA from calf thymus (ct-DNA) and fish sperm DNA from salmon testes. The concentration of the DNA solution was determined by spectrophotometry at 260 nm using an extinction coefficient of  $6600 \text{ L mol}^{-1} \text{ cm}^{-1}$  ( $50 \mu\text{g/L}$ ).

#### 5.1.2 Chromatography

Silica 60 F254 aluminium sheets (thickness 0.2 mm each) and aluminium oxide 60 F254 aluminium sheets from Merck ([www.merck.de](http://www.merck.de)) were used for analytical thin-layer chromatography. Column chromatography was carried out using silica gel 60 (40 – 63  $\mu\text{m}$ ) as the stationary phase for non-polar substances and neutral or acidic aluminium oxide (50 – 150  $\mu\text{m}$ ) as stationary phase for polar substances (all from Merck).

### 5.1.3 Spectra and Imaging

<sup>1</sup>H-NMR spectra were recorded on a 300 MHz NMR spectrometer (Avance 300 from Bruker BioSpin GmbH). The internal standard was tetramethylsilan (TMS). The chemical shifts are given in ppm. The following abbreviations were used to describe the signals: s = singlet, d = doublet, t = triplet, m = multiplet. Mass spectra were recorded with a Thermoquest TSQ 7000 (electro spray ionization, ESI). Absorption spectra in standard quartz cuvettes (1 x 1 x 3 cm) were acquired on a Cary 50 Bio UV-visible spectrometer from Varian ([www.varian.com](http://www.varian.com)), melting curves were carried out at 260 nm using a Cary Varian 100 spectrophotometer ([www.varianinc.com](http://www.varianinc.com)) with a temperature controller. Fluorescence spectra and resonance light scattering spectra were performed on an Aminco Bowman AB2 luminescence spectrometer equipped with a 150-W continuous wave xenon lamp as the excitation source. Decay times of the luminescent probes were determined using a K2 spectrometer from ISS. The measurements were performed in low frequency mode with a pulsed 100 mW cw argon ion laser as light source. The instrument was also used for polarization measurements, using the xenon lamp at an excitation wavelength of 450 nm. The emission was monitored after passing an RG 610 filter. The orientation of the polarizers was checked with solutions of glycogen.

Viscosity experiments were performed on a KPG Ubbelohde viscosimeter ([www.schottinstruments.com](http://www.schottinstruments.com)) immersed in a temperature bath thermostatted to 25 °C.

## 5.2 Synthesis and Purification of Dyes

### 5.2.1 Synthesis of $[\text{Ru}(\text{bpy})_2(\text{phen-NH}_2)]^{2+}$

A total of 0.97 g (2 mmol) of  $\text{Ru}(\text{bpy})_2\text{Cl}_2$  and 0.4 g of (2 mmol) 5-amino-1,10-phenanthroline were refluxed in 30 mL of MeOH/water (1:1) for 12 hours. After cooling to room temperature, methanol was removed by rotary evaporation and the complex was precipitated by adding an excess of  $\text{NH}_4\text{PF}_6$  to the remaining water solution. Purification was achieved by column chromatography on alumina using toluene:acetonitrile (1:2) as eluent. The first band was collected.<sup>1</sup>

Yield: 1.38 g (1.5 mmol, 77%), red powder,  $\text{C}_{32}\text{H}_{25}\text{F}_{12}\text{N}_7\text{P}_2\text{Ru}$  (898.60 g/mol).

$R_f$  (aluminium oxide, toluene:acetonitril 1:2 v/v): 0.81

ES MS:  $m/z$  328.5 [ $\text{M}^{2+}$ ], 802.2 [ $\text{M}^{2+} + \text{PF}_6^-$ ].

## 5.2.2 Synthesis of $[\text{Ru}(\text{bpy})_2(\text{phen-ITC})]^{2+}$

A total of 0.1 g (0.01 mmol) of  $[\text{Ru}(\text{bpy})_2(\text{phen-NH}_2)]^{2+}$  was dissolved in 1 mL of dry acetone. Fine  $\text{CaCO}_3$  powder (40 mg, 0.4 mmol) and 10  $\mu\text{L}$  (0.13 mmol) of thiophosgene were added to this solution and the mixture was stirred for 1 h at room temperature, followed by 2.5 h of heating under reflux. After cooling to room temperature, the  $\text{CaCO}_3$  was filtered and the acetone removed under reduced pressure.<sup>1</sup>

Yield: 82 mg (87 mmol, 82 %), red powder,  $\text{C}_{33}\text{H}_{23}\text{F}_{12}\text{N}_7\text{P}_2\text{RuS}$  (940.65 g/mol)

$R_f$  (aluminium oxide, acetonitril: water 80:20 v/v): 0.94, 0.80.

ESI MS:  $m/z$  325.1  $[\text{M}^{2+}]$ , 796.1  $[\text{M}^{2+} + \text{PF}_6^-]$ .

### 5.2.3 Synthesis of 2-(Boc-amino) ethyl bromide (Boc-AEB)

To a solution of 10 g (49 mmol) of 2-aminoethyl bromide hydrobromide in 250 mL of MeOH and 70 mL of triethylamine, 21.3 g (98 mmol) di-tert.-butyl dicarbonate was added. The reaction mixture was stirred at 60 °C for 1 h and then at room temperature for 14 h. The mixture was concentrated by evaporating MeOH, then 50 mL of CH<sub>2</sub>Cl<sub>2</sub> were added. The solution was washed successively with 1M HCl, brine, saturated NaHCO<sub>3</sub> solution and brine, dried over Na<sub>2</sub>SO<sub>4</sub> and the CH<sub>2</sub>Cl<sub>2</sub> was removed by rotary evaporation. The residue was purified by silica gel column chromatography (CH<sub>2</sub>Cl<sub>2</sub>) to give pure 2-(Boc-amino) ethyl bromide as colorless oil.<sup>250</sup>

Yield: 8.56 g (38.2 mmol, 78 %), colorless oil, C<sub>7</sub>H<sub>14</sub>BrNO<sub>2</sub> (224.10 g/mol)

R<sub>f</sub> (silica gel, CH<sub>2</sub>Cl<sub>2</sub>): 0.57

<sup>1</sup>H NMR (d<sub>3</sub>-chloroform, TMS): δ 1.45 (s, 9H), 3.52 (m, 4H), 4.94 (s, 1H).

### 5.2.4 Synthesis of 3-(Boc-amino) propyl bromide (Boc-APB)

To a solution of 10 g (45 mmol) of 3-amino propyl bromide hydrobromide in MeOH and triethylamine, di-tert.-butyl dicarbonate was added. The reaction mixture was stirred at 60

°C for 1 h and then at room temperature for 14 h. The mixture was concentrated by evaporating MeOH, then 50 mL of CH<sub>2</sub>Cl<sub>2</sub> were added. The solution was washed successively with 1M HCl, brine, saturated NaHCO<sub>3</sub> solution and brine, dried over Na<sub>2</sub>SO<sub>4</sub> and the CH<sub>2</sub>Cl<sub>2</sub> was removed by rotary evaporation. The residue was purified by silica gel column chromatography (CH<sub>2</sub>Cl<sub>2</sub>) to give pure 3-(Boc-amino) propyl bromide as colorless oil.<sup>250</sup>

Yield: 84.5 g (3.55 mmol, 79 %), colorless oil, C<sub>8</sub>H<sub>16</sub>BrNO<sub>2</sub> (238.12).

R<sub>f</sub> (silics gel, CH<sub>2</sub>Cl<sub>2</sub>): 0.59

<sup>1</sup>H NMR (d3-chloroform, TMS): δ 1.44 (s, 9H), 2.05 (m, 2H), 3.26 (q, 2H), 3.44 (t, 2H), 4.64 (s, 1H).

### 5.2.5 Synthesis of N,N'-tetramethyl-N,N'-di-(2-(Boc-amino)ethyl) butyl ammonium

**4a:** n = 2, m = 4

**4b:** n = 3, m = 3

**4c:** n = 3, m = 4

**4d:** n = 2, m = 6

**4e:** n = 3, m = 6

**4a)** To 410 μL (2.4 mmol) of TMBD, 5 g (22 mmol) of 2-(Boc-amino) ethyl bromide were added and the mixture was stirred for 12 h. To the resulting clear paste, 20 mL ethyl acetate

was added to form a white precipitate. The precipitate was filtered and dried over P<sub>2</sub>O<sub>5</sub> under vacuum.

Yield: 1.15 g (1.94 mmol, 87 %), white powder, C<sub>22</sub>H<sub>48</sub> Br<sub>2</sub>N<sub>4</sub>O<sub>4</sub> (592.46 g/mol).

<sup>1</sup>H NMR (d<sub>3</sub>-chloroform, TMS): δ 1.31 (s, 18H), 1.76 (m, 2H), 3.02 (s, 12H), 3.32 (m, 8H), 3.43 (m, 4H).

**4b)** To 525 μL (2.9 mmol) of TMPD, 7 g (29 mmol) of 2-(Boc-amino) propyl bromide were added and the mixture was stirred for 12 h. To the resulting clear paste, 20 mL ethyl acetate was added to form a white precipitate. The precipitate was filtered and dried over P<sub>2</sub>O<sub>5</sub> under vacuum.

Yield: 1.69 g (2.79 mmol, 89 %), white powder, C<sub>23</sub>H<sub>50</sub> Br<sub>2</sub>N<sub>4</sub>O<sub>4</sub> (606.48 g/mol).

<sup>1</sup>H NMR (d<sub>3</sub>-chloroform, TMS): δ 1.33 (s, 18H), 1.85 – 1.95 (m, 4H), 2.19 – 2.25 (m, 2H), 3.06 (s, 12H), 3.12. (t, 4H), 3.3 – 3.34 (m, 8H).

**4c)** To 380 μL (2.1 mmol) of TMBD, 5 g (21 mmol) of 2-(Boc-amino) propyl bromide were added and the mixture was stirred for 12 h. To the resulting clear paste, 20 mL ethyl acetate was added to form a white precipitate. The precipitate was filtered and dried over P<sub>2</sub>O<sub>5</sub> under vacuum.

Yield: 1.05 g (1.70 mmol, 83 %), white powder, C<sub>24</sub>H<sub>52</sub> Br<sub>2</sub>N<sub>4</sub>O<sub>4</sub> (620.51 g/mol).

<sup>1</sup>H NMR (d<sub>3</sub>-chloroform, TMS): δ 1.33 (s, 18H), 1.85 – 1.95 (m, 4H), 2.19 – 2.25 (m, 2H), 3.06 (s, 12H), 3.12. (t, 4H), 3.30 – 3.34 (m, 8H).

**4d)** To 470 μL (2.1 mmol) of TMHD, 5 g (22 mmol) of 2-(Boc-amino) ethyl bromide were added and the mixture was stirred for 12 h. To the resulting clear paste, 20 mL ethyl acetate was added to form a white precipitate. The precipitate was filtered and dried over P<sub>2</sub>O<sub>5</sub> under vacuum.

Yield: 1.32 g (2.13 mmol, 95 %), white powder, C<sub>24</sub>H<sub>52</sub> Br<sub>2</sub>N<sub>4</sub>O<sub>4</sub> (620.51 g/mol).

<sup>1</sup>H NMR (d<sub>3</sub>-chloroform, TMS): δ 1.33 (s, 18H), 1.85 – 1.95 (m, 4H), 2.19 – 2.25 (m, 2H), 3.06 (s, 12H), 3.12. (t, 4H), 3.30 – 3.34 (m, 8H).

**4e**) To 450  $\mu\text{L}$  (2.1 mmol) of TMHD, 5 g (21 mmol) of 2-(Boc-amino) propyl bromide were added and the mixture was stirred for 12 h. To the resulting clear paste, 20 mL ethyl acetate was added to form a white precipitate. The precipitate was filtered and dried over  $\text{P}_2\text{O}_5$  under vacuum.

Yield: 1.21 g (1.87 mmol, 89 %), white powder,  $\text{C}_{26}\text{H}_{56}\text{Br}_2\text{N}_4\text{O}_4$  (648.56 g/mol).

$^1\text{H}$  NMR ( $d_3$ -chloroform, TMS):  $\delta$  1.33 (s, 18H), 1.85 – 1.95 (m, 4H), 2.19 – 2.25 (m, 2H), 3.06 (s, 12H), 3.12. (t, 4H), 3.30 – 3.34 (m, 8H).

### 5.2.6 Synthesis of N,N'-tetramethyl-N,N'-di-(2-amino ethyl) butyl ammonium

**3a:**  $n = 2$ ,  $m = 4$

**3b:**  $n = 3$ ,  $m = 3$

**3c:**  $n = 3$ ,  $m = 4$

**3d:**  $n = 2$ ,  $m = 6$

**3e:**  $n = 3$ ,  $m = 6$

1.15 g (1.94 mmol) of N,N'-tetramethyl-N,N'-di-(2-(Boc-amino)ethyl) butyl ammonium were dissolved in water and refluxed for 12 h. Then, the water was removed by rotary evaporation and the resulting clear paste was dried over KOH under vacuum to remove residual water to get a white solid. The same procedure was performed with **4b-e** to remove the Boc protecting group to obtain salt **3b-e**.

**3a:** Yield: 732 mg (1.87 mmol 97 %), white solid,  $\text{C}_{12}\text{H}_{32}\text{Br}_2\text{N}_4$  (392.22 g/mol).

$^1\text{H}$  NMR (d<sub>2</sub>-water, TMS):  $\delta$  1.84 (m, 4H), 3.12 (s, 12H), 3.42 - 3.5 (m, 8H), 3.6 - 3.66 (m, 4H).

**3b**: Yield: 1.05 mg (2.58 mmol, 89 %), white solid, C<sub>13</sub>H<sub>34</sub>Br<sub>2</sub>N<sub>4</sub> (406.25 g/mol).

$^1\text{H}$  NMR (d<sub>2</sub>-water, TMS):  $\delta$  2.10 - 2.21 (m, 4H), 2.25 - 2.36 (m, 2H), 3.03 (t, 4H), 3.11 (s, 12H), 3.36 - 3.48 (m, 8H).

**3c**: Yield: 689 mg (1.64 mmol, 96 %), white solid, C<sub>14</sub>H<sub>36</sub>Br<sub>2</sub>N<sub>4</sub> (420.27 g/mol).

$^1\text{H}$  NMR (d<sub>2</sub>-water, TMS):  $\delta$  1.80 (m, 4H), 2.12 (m, 2H), 3.03 (m, 16H), 3.37 (m, 8H).

**3d**: Yield: 868 mg (2.06 mmol, 97 %), white solid, C<sub>14</sub>H<sub>36</sub>Br<sub>2</sub>N<sub>4</sub> (420.27 g/mol).

$^1\text{H}$  NMR (d<sub>2</sub>-water, TMS):  $\delta$  1.38 (m, 4H), 1.76 (m, 4H), 3.12 (s, 12H), 3.32 - 3.4 (m, 4H), 3.43 - 3.51 (m, 4H), 3.58 - 3.67 (m, 4H).

**3e**: Yield: 872 mg (2.06 mmol, 98 %), white solid, C<sub>64</sub>H<sub>42</sub>Br<sub>2</sub>N<sub>4</sub> (448.33 g/mol).

$^1\text{H}$  NMR (d<sub>2</sub>-water, TMS):  $\delta$  1.33 (m, 4H), 1.70 (m, 4H), 2.08 (m, 4H), 2.99 (s, 12H), 3.08 (t, 4H), 3.2 - 3.36 (m, 8H).

## 5.2.7 Synthesis of Probe 1

To a solution of 100 mg (0.1 mmol) of  $[\text{Ru}(\text{bpy})_2(\text{phen-ITC})]^{2+}$  in 3 mL of acetone and 100  $\mu\text{L}$  of  $\text{NEt}_3$ , 94 mg of 2-amino-ethyl-tetramethyl ammonium in 2 mL of MeOH were added. The mixture was stirred for 3 h at room temperature, then the solvent was removed. The product was purified by neutral alumina chromatography with a mixture of acetonitrile/water (80:20, vv) as the eluent. The third band was collected. After the removal of acetonitrile,  $\text{NH}_4\text{PF}_6$  was added to the remaining aqueous solution to form a red precipitate which was filtered and dried over silica gel.

Yield: 66 mg (0.056 mmol, 56%), red solid,  $\text{C}_{38}\text{H}_{38}\text{F}_{18}\text{N}_9\text{P}_3\text{RuS}$  (1188.8 g/mol)

$^1\text{H}$  NMR ( $d_2$ -water):  $\delta$  3.13 (s, 9H), 3.53 (m, 2H), 4.03 (t, 2H), 7.1 (m, 2H), 7.31 (t, 2H), 7.52 – 7.65 (m, 4H), 7.82 – 7.91 (m, 4H), 7.98 (m, 2H), 8.10 – 8.14 (m, 3H), 8.41 – 8.50 (m, 6H).

## 5.2.8 Synthesis of the Dinuclear Complexes

**2a:** To a solution of 434 mg (0.46 mmol) of  $[\text{Ru}(\text{bpy})_2(\text{phen-ITC})]^{2+}$  in acetone, 60 mg (0.15 mmol) of **3a** in methanol and 100  $\mu\text{L}$  of  $\text{NEt}_3$  were added and stirred for 3 h at room temperature. Then, the acetone was removed and water was added to the remaining solution. Afterwards,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate, which was filtered and dried over  $\text{P}_2\text{O}_5$ . The red solid was purified by column chromatography on acidic alumina as stationary phase. The first band was eluted with a mixture of acetonitrile/water (vv, 90:10), the second band, containing the product, by using acetonitrile/water (vv, 80:20) as eluent. After the acetonitrile was removed,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate that was filtered and dried. The resulting red powder was resolved in acetone and the product precipitated by the addition of water, filtered and dried under vacuum over  $\text{KOH}$ .

Yield: 122.6 mg (0.051 mmol, 34 %), red solid,  $\text{C}_{78}\text{H}_{78}\text{F}_{36}\text{N}_{18}\text{P}_6\text{Ru}_2\text{S}_2$  (2404.2 g/mol)

$^1\text{H}$  NMR ( $d_6$ -acetone, TMS): DB24: 2.12 (m, 4H), 3.35 (s, 12H), 3.66 – 3.76 (m, 8H), 4.26 (m, 4H), 7.40 (m, 4H), 7.62 (m, 4H), 7.88 (m, 8H), 8.14 – 8.27 (m, 12H), 8.41 (m, 6H), 8.71–8.85 (m, 12H)

**2b:** To a solution of 418 mg (0.45 mmol) of  $[\text{Ru}(\text{bpy})_2(\text{phen-ITC})]^{2+}$  in acetone, 60 mg (0.15 mmol) of **3b** in methanol and 100  $\mu\text{L}$  of  $\text{NEt}_3$  were added and stirred for 3 h at room temperature. Then, the acetone was removed and water was added to the remaining solution. Afterwards,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate, which was filtered and dried over  $\text{P}_2\text{O}_5$ . The red solid was purified by column chromatography on acidic alumina as stationary phase. The first band was eluted with a mixture of acetonitrile/water (vv, 90:10), the second band, containing the product, by using acetonitrile/water (vv, 80:20) as eluent. After the acetonitrile was removed,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate that was filtered and dried. The resulting red powder was resolved in acetone and the product precipitated by the addition of water, filtered and dried under vacuum over KOH.

Yield: 148.7 mg (0.062 mmol, 41 %), red solid,  $\text{C}_{79}\text{H}_{80}\text{F}_{36}\text{N}_{18}\text{P}_6\text{Ru}_2\text{S}_2$  (2418.2 g/mol)

$^1\text{H}$  NMR (d6-acetone, TMS): DB33:  $\delta$  2.33 (m, 4H), 2.61 (m, 2H), 3.32 (s, 12H), 3.64 (m, 8H), 3.80 (m, 4H), 7.4 (m, 4H), 7.61 (m, 4H), 7.89 (m, 8H), 8.10 – 8.25 (m, 12H), 8.35 – 8.43 (m, 6H), 8.68 – 8.83 (m, 12H),

**2c:** To a solution of 404 mg (0.43 mmol) of  $[\text{Ru}(\text{bpy})_2(\text{phen-ITC})]^{2+}$  in acetone, 60 mg (0.14 mmol) of **3c** in methanol and 100  $\mu\text{L}$  of  $\text{NEt}_3$  were added and stirred for 3 h at room temperature. Then, the acetone was removed and water was added to the remaining solution. Afterwards,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate, which was filtered and dried over  $\text{P}_2\text{O}_5$ . The red solid was purified by column chromatography on acidic alumina as stationary phase. The first band was eluted with a mixture of acetonitrile/water (vv, 90:10), the second band, containing the product, by using acetonitrile/water (vv, 80:20) as eluent. After the acetonitrile was removed,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate that was filtered and dried. The resulting red powder was resolved in acetone and the product precipitated by the addition of water, filtered and dried under vacuum over KOH.

Yield: 95.5 mg (0.039 mmol, 28%), red solid,  $\text{C}_{80}\text{H}_{86}\text{F}_{36}\text{N}_{18}\text{P}_6\text{Ru}_2\text{S}_2$  (2436.2 g/mol)

$^1\text{H}$  NMR (d6-acetone, TMS): DB34: 2.26 (m, 4H), 3.27 (s, 12H), 3.63 (m, 12H), 7.38 (m, 4H), 7.62 (m, 4H), 7.88 (m, 8H), 8.10 – 8.24 (12H), 8.35- 8.42 (m, 6H), 8.74 – 8.85 (m, 12H)

**2d:** To a solution of 404 mg (0.43 mmol)  $[\text{Ru}(\text{bpy})_2(\text{phen-ITC})]^{2+}$  in acetone, 60 mg (0.14 mmol) of **3d** in methanol and 100  $\mu\text{L}$  of  $\text{NEt}_3$  were added and stirred for 3 h at room

temperature. Then, the acetone was removed and water was added to the remaining solution. Afterwards,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate, which was filtered and dried over  $\text{P}_2\text{O}_5$ . The red solid was purified by column chromatography on acidic alumina as stationary phase. The first band was eluted with a mixture of acetonitrile/water (vv, 90:10), the second band, containing the product, by using acetonitrile/water (vv, 80:20) as eluent. After the acetonitrile was removed,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate that was filtered and dried. The resulting red powder was resolved in acetone and the product precipitated by the addition of water, filtered and dried under vacuum over KOH

Yield: 105 mg (0.043 mmol, 31 %), red solid,  $\text{C}_{80}\text{H}_{86}\text{F}_{36}\text{N}_{18}\text{P}_6\text{Ru}_2\text{S}_2$  (2435.7 g/mol)

$^1\text{H}$  NMR (d6-acetone, TMS): DB26: 2.26 (m, 4H), 3.27 (s, 12H), 3.63 (m, 12H), 7.38 (m, 4H), 7.62 (m, 4H), 7.88 (m, 8H), 8.10 – 8.24 (12H), 8.35- 8.42 (m, 6H), 8.74 – 8.85 (m, 12H)

**2e:** To a solution of 378 mg (0.40 mmol) of  $[\text{Ru}(\text{bpy})_2(\text{phen-ITC})]^{2+}$  in acetone, 60 mg (0.13 mmol) of **3e** in methanol and 100  $\mu\text{L}$  of  $\text{NEt}_3$  were added and stirred for 3 h at room temperature. Then, the acetone was removed and water was added to the remaining solution. Afterwards,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate, which was filtered and dried over  $\text{P}_2\text{O}_5$ . The red solid was purified by column chromatography on acidic alumina as stationary phase. The first band was eluted with a mixture of acetonitrile/water (vv, 90:10), the second band, containing the product, by using acetonitrile/water (vv, 80:20) as eluent. After the acetonitrile was removed,  $\text{NH}_4\text{PF}_6$  was added to form a red precipitate that was filtered and dried. The resulting red powder was resolved in acetone and the product precipitated by the addition of water, filtered and dried under vacuum over KOH.

Yield: 80 mg (0.033 mmol, 25 %), red solid,  $\text{C}_{82}\text{H}_{90}\text{F}_{36}\text{N}_{18}\text{P}_6\text{Ru}_2\text{S}_2$  (2464.2 g/mol)

$^1\text{H}$  NMR (d6-acetone, TMS): DB36: 2.26 (m, 4H), 3.27 (s, 12H), 3.63 (m, 12H), 7.38 (m, 4H), 7.62 (m, 4H), 7.88 (m, 8H), 8.10 – 8.24 (12H), 8.35- 8.42 (m, 6H), 8.74 – 8.85 (m, 12H)

## 6. Summary

### 6.1 In English

This thesis describes the synthesis of DNA probes derived from ruthenium ligand complexes (RLCs). The binding mode of those RLCs to DNA was investigated and the concentration of nucleic acid determined via the Resonance Light Scattering (RLS) technique.

Chapter 1 gives a short overview of the use of ruthenium complexes and their advantages over organic dyes. There, the luminescence emission mechanism of ruthenium ligand complexes is explained in detail. The three possible binding modes to DNA are described.

Chapter 2 describes the mainstream theory of the RLS technique by Pasternack et al.. Since the introduction and its proof as a valuable tool in analytical chemistry was made, there were a large number of further developments. The development of various techniques including the total internal reflected resonance light scattering (TIR-RLS) and backscattering light (BSL), surface enhanced light scattering (SELS), resonance light scattering imaging (RLSI), flow injection resonance light scattering (FI-RLS) and wavelength ratiometric RLS technique (WRRLS) as well as the RLS particles are discussed.

In Chapter 3 the binding modes of the RLC derived probes to DNA were investigated. Absorption and fluorescence spectra as well as polarization and melting studies of the probes were performed in absence and presence of DNA resulting in the conclusion that all probes bind to DNA in an intercalative mode. Viscosity measurements, the most critical binding test, especially support this conclusion.

Chapter 4 presents the determination of DNA via RLS technique using the newly designed RLCs. The optimal conditions for the assay were determined. The probe **2b** proved to be best because the assay could be performed at neutral pH. The optimal pH using probe **1** and **2a** was pH 3. The pH optimum lies in the basic range for the other dinuclear RLCs. The LOD of **2b** was calculated to be  $1.6 \text{ ng mL}^{-1}$  for ct-DNA and  $2.7 \text{ ng mL}^{-1}$  for fs-DNA with a wide linear range of  $30 - 1800 \text{ ng mL}^{-1}$  under optimum conditions. The method presented here does not require surfactants and can be performed under neutral pH conditions. The low LODs of this assay are obtained in a very simple way and are definitely comparable to other RLS based methods, but also to well established fluorometric methods. Hence, the RLS assay represents a valuable tool for DNA determination.

Chapter 5 describes a description of the synthetic pathways and purification of the ruthenium complexes with yields in the range of 20- 30 % used in chapter 3 and 4. The proof of structure and purity was provided by  $^1\text{H}$  NMR data.

## 6.2 In German

Diese Arbeit beschreibt die Synthese von DNA Sonden, die sich von Rutheniumligandenkomplexen (RLC) ableiten. Die Bindungseigenschaften dieser RLCs wurden untersucht und Konzentration an DNA mittels der Resonanzlichtstreuung (RLS) bestimmt.

Kapitel 1 beschreibt den Mechanismus auf dem die Lumineszenz der RLCs beruht, sowie deren Vorteile gegenüber organischen Farbstoffen bezogen auf ihre chemischen und photochemischen Eigenschaften. Des weiteren werden die drei möglichen kovalenten Bindungen zu DNA gezeigt und ein Überblick über die vielfältigen Anwendungsmöglichkeiten von RLCs gegeben.

Kapitel 2 beschreibt die am weitesten verbreitete Theorie der RLS Technik nach Pasternack et al. Seit der Einführung der RLS Technik 1993, hat sie sich als ein wertvolles Werkzeug in der analytischen Chemie erwiesen. Eine große Anzahl von Weiterentwicklungen folgten in den nächsten Jahren, unter anderem die Total Internal Reflected Resonance Light Scattering Technik (TIR-RLS), die Backscattering Light Technik (BSL), die Surface Enhanced Light Scattering Technik (SELS), die Resonance Light Scattering Imaging Technik (RLSI), die Flow Injection Resonance Light Scattering Technik (FIA-RLS) und die Wavelength Ratiometric RLS Technik (WR-RLS) sowie die Entwicklung von RLS Partikeln. Die genannten Techniken werden im Einzelnen beschrieben.

In Kapitel 3 werden die Bindungseigenschaften der in dieser Arbeit synthetisierten RLCs (siehe Kapitel 5) mit DNA untersucht. Dafür wurden Absorptions- und Fluoreszenzspektren aufgenommen, sowie Polarisationsmessungen und Schmelzkurven in An- und Abwesenheit von DNA durchgeführt. Die Ergebnisse der Messungen lassen darauf schließen, daß sich die Sonden in die DNA einlagern. Besonders die Viskositätsmessungen, der kritischste Test, unterstreichen diese Schlußfolgerung.

Kapitel 4 zeigt die Bestimmung von DNA Konzentrationen via Resonanzlichtstreuung mittels RLCs deren Synthese in Kapitel 5 beschrieben wird. Die optimalen Bedingungen des Assays wurden ermittelt, wobei sich die Sonde **2b** als die am besten geeignete

herausstellte. In diesem Falle konnte der Assay unter neutralen Bedingungen durchgeführt werden. Dagegen liegt bei den Proben **1** und **2a** der optimale pH im sauren; der der Sonden **2c - e** im basischen Bereich. Unter optimalen Bedingungen, d.h. pH 7 und einer Konzentration von **2b** von 1  $\mu\text{M}$ , konnte eine Nachweisgrenze für ct-DNA von 1.6  $\text{ng mL}^{-1}$  und von 2.7  $\text{ng mL}^{-1}$  für fs-DNA bestimmt werden. Der lineare Bereich erstreckt sich von 30 bis 1800  $\text{ng mL}^{-1}$ . Die hier präsentierte Methode benötigt keine Zusätze ( in der Regel Tenside wie CTMAB) und kann unter neutralen pH durchgeführt werden. Mit dieser einfachen Methode können niedrige Nachweisgrenzen erreicht werden, die mit anderen auf RLS Technik basierenden, aber auch mit bereits gut etablierten fluorimetrischen Methoden vergleichbar sind. Deswegen stellt dieser RLS Assay ein wertvolles Werkzeug zur Bestimmung von DNA.

Kapitel 5 beschreibt die Synthese und Reinigung der in Kapitel 3 und 4 verwendeten RLC. Die Ausbeuten liegen zwischen 20 und 30 %. Die Struktur wurde durch  $^1\text{H}$  NMR Spektroskopie belegt.

## 7. Curriculum Vitae

Vor- und Nachname: Doris Burger  
Adresse: Tulpenweg 2  
93080 Pentling  
Telefon: 0179/9215312  
E-Mail: burger.doris@web.de  
Geburtsdatum und –Ort: 15. 01. 1980 in Weiden i. d. Opf.  
Familienstand: ledig  
Staatsangehörigkeit: deutsch

### **Ausbildung:**

Ab März 2005 Promotion, Institut für analytische Chemie, Chemo- und Biosensorik bei Prof. O. S. Wolfbeis an der Universität Regensburg  
Thema der Dissertation: Determination of DNA via Resonance Light Scattering Technique Using New Probes Derived from Ruthenium Ligands Complexes and Investigation of their Binding Mode

Mai 2004 - Februar 2005 Diplomarbeit, Institut für Analytische Chemie, Chemo- und Biosensorik an der Universität Regensburg  
Thema: Phosphoreszierende polykationische Ruthenium-Liganden-Komplexe als potentielle DNA-Interkalatoren.

Oktober 1999 - März 2004 Studium der Chemie an der Universität Regensburg

September 1990 - Juli 1999 Erlangung der allg. Hochschulreife am Gymnasium Eschenbach, Landkreis Neustadt a. d. Waldnaab

## **Studienbegleitende Tätigkeiten:**

Praktika:	Betreuung der Praktika für organische und anorganische Chemie für Mediziner und Zahnmediziner. Anleitung und Vermittlung grundlegender chemischer Sachverhalte und Techniken.
Lehre:	Tutorien und Nachhilfe für Medizinstudenten zur Verbesserung und Vertiefung chemischen Wissens zur Klausurvorbereitung.
Sonstiges:	Mithilfe an der Organisation und Durchführung des deutschen Biosensor Symposiums 2005 in Regensburg und der Konferenz über Methods and Applications of Fluorescence 2007 in Salzburg..

## **Kenntnisse und Fähigkeiten:**

Englisch:	sehr gute Kenntnisse in Wort und Schrift
Französisch:	Grundlagen
Italienisch:	Grundlagen
EDV- Kenntnisse:	MS-Office, Maple, Origin
