Antipsoriatic Anthrones with Modulated Redox Properties. 1. Novel 10-Substituted 1,8-Dihydroxy-9(10H)-anthracenones as Inhibitors of 5-Lipoxygenase

Klaus Müller,* Dieter Gürster, Susanne Piwek, and Wolfgang Wiegrebe

Pharmazeutische Chemie I, Universität Regensburg, Institut für Pharmazie, D-93040 Regensburg, Germany

Received August 13, 1993*

The syntheses, the biological evaluation, and the structure–activity relationships of a novel series of 1,8-dihydroxy-9(10H)-anthracenones bearing acyl-, alkyl-, or alkylidene-linked aromatic substituents in the 10-position are described. The phenylacyl and phenylalkylidene analogs were far more potent inhibitors of 5-lipoxygenase (5-LO) from bovine polymorphonuclear leukocytes (IC50 values in the 10⁻⁷ M range) than the antipsoriatic drug anthralin, whereas phenylalkyl analogs were only weak inhibitors. Among the active compounds were both potent generators of hydroxyl radicals, as determined by deoxyribose degradation, and strong reducers of the stable free radical 2,2-diphenyl-1-picrylhydrazyl (DPPH). However, several derivatives of this series maintained 5-LO inhibitory activity but did not generate hydroxyl radicals and were not reactive with DPPH. In particular, phenylacyl analogs were also 6 times more efficient in inhibition of lipid peroxidation in model membranes than anthralin. Structure–activity relationships have shown that the presence of free phenolic groups in the attached aromatic ring is beneficial but not required for 5-LO inhibitory potency. The inhibitory potency in the 10-phenylacyl series increased with the length of the acyl chain with three methylene units being the optimum, suggesting a specific enzyme interaction which would not be expected for nonspecific redox inhibitors.

Psoriasis is a widespread, chronic inflammatory and scaling skin disease, mainly characterized by increased cell proliferation of the epidermis.¹ There is evidence, however, that hyperproliferation alone is not sufficient to produce a psoriatic lesion, and it has been suggested that the inflammatory component is an important part of the disease process.² The etiology is as yet unknown, but psoriasis is known to be associated with numerous biochemical abnormalities.³ A characteristic of lesional skin is the elevated level of oxygenation products of arachidonic acid. In particular, evidence has been provided showing the enhanced production of 5-lipoxygenase (5-LO) products such as leukotriene B4 (LTB4) and 5-hydroxyeicosatetraenoic acid (5-HETE) in psoriasis.⁴ Moreover, the effects of 5-LO products in the skin correlate with several pathological features of psoriasis, in particular, leukocyte migration and enhanced cell proliferation.⁷ Thus, regulation of 5-LO pathways has become an important target for therapeutic intervention.⁶⁻¹⁰

Probably the most commonly used topical agent for the treatment of psoriasis is anthralin (1,8-dihydroxy-9(10H)-anthracenone, dithranol, 1), which is free of mutagenic property and even exhibits some antimutagenic activity.¹¹ However, anthralin therapy causes unpleasant side effects. For example, nonaffected skin surrounding a psoriatic lesion to which anthralin is applied is frequently irritated and stained.¹² Thus, patient compliance is reduced. The mechanism of the irritancy and the mode of action of anthralin are still not fully understood, but substantial evidence suggests that free radicals and active oxygen species are involved.¹³⁻¹⁹ Although these species may be responsible for the skin irritation and the production of staining products, they are presumably central to the clinical efficacy of the drug. Hence it seems difficult to separate main and side effects. Anthralin may act both as an antioxidant and as a prooxidant.²⁰ In addition, it was shown to inhibit the 5- and 12-LO pathways of arachidonic acid metabolism in vitro.²¹,²²,²³ The biosynthesis of eicosanoids occurs via the formation of free radicals.²³ Therefore, compounds with antioxidant properties would be expected to be potential inhibitors of 5-LO.²⁴⁻²⁸ Furthermore, oxygen free radicals, which are inflammatory mediators of considerable importance, may be inactivated by such compounds.²⁹,³⁰ Although there have been attempts to develop new therapeutically effective derivatives of anthralin, such as triacetoxanthrancene³¹ and butantrone³² (3) for which initial reports were promising, later reports have indicated that these compounds were less effective and more irritating than anthralin itself.³³,³⁴ Accordingly, there is still need for improved antipsoriatic anthrones that are effective at low dose with low irritancy.

The aim of the present study was to modulate the intensity of active oxygen release by 1,8-dihydroxy-9(10H)-anthracenones, which may permit a separation of antipsoriatic and inflammatory effects. This modulation can be achieved by partially blocking the C-10 position, which is responsible for the production of the superoxide radical,¹⁴ a precursor in the formation of the hydroxyl radical by anthralin.¹⁵

A series of anthralin analogs bearing acyl-, alkyl-, or alkylidene-linked aromatic substituents in the 10-position was synthesized to investigate the effects on hydroxyl radical formation and 5-LO inhibition. Structure–activity relationships are discussed with respect to the following redox properties of the compounds which were recently established for anthralin:¹⁶ reactivity against the stable free radical 2,2-diphenyl-1-picrylhydrazyl (DPPH), prooxidant potential as determined by deoxyribose degradation, and inhibitory effect on lipid peroxidation in model membranes.

Chemistry

Introduction of the 10-acyl functionality onto the anthrone nucleus (compounds 4a–u) was achieved by reaction of the appropriate acyl chlorides with anthralin
under weakly basic conditions, where acylation takes place at the C-10 position via the carbanion (Scheme I).

The required acyl chlorides were prepared from the corresponding acids according to literature methods.

Because ether cleavage of 4e with boron tribromide resulted in loss of the acyl function at C-10, the desired phenolic analogs 4r-u were prepared by hydrogenolytic cleavage of benzyl ethers 4d-f and 4l (Scheme I).

Scheme II illustrates the synthesis of the 10-phenylalkylidene derivatives 7a-r. To this end, a new method for attaching carbon substituents to the 10-position of anthralin had to be established. Attempts to obtain the desired compounds by condensation of anthralin with various benzaldehydes in the presence of piperidine or other basic additives failed. However, the use of α-chloro methyl ethers proved to be successful. Thus, conversion of suitable aldehydes to their dimethyl acetals followed by treatment with acetyl chloride provided the corresponding α-chloro methyl ethers 5a–m. In most cases, α-chloro methyl ethers were used in crude form because purification led to decomposition. Alkylation of anthralin with α-chloro methyl ethers in the presence of the non-nucleophilic base 1,3-diazacyclo[5.4.0]undec-7-ene (DBU) at 0 °C gave 1,3-dihydroxy-10-(1-methoxy-α-phenylalkyl)-9(10H)-anthracenones 6a–m. Base-catalyzed (pyridine) elimination of a molecule of methanol afforded 7a-h and 7j–m in good yields. Derivative 7o was obtained by acid hydrolysis of benzonitrile 7e and subsequent esterification of the acid 7n. The 10-(hydroxyphenyl)methylene derivatives 7p–r were obtained by deprotection of the corresponding methyl ethers 7f–h with boron tribromide in methylene chloride. Under identical conditions as described for 7a–h, conversion of 6i (n = 1) afforded an isomeric mixture of 7i and 8 in a 65:35 ratio. 7i was prepared selectively from 6i by reaction with DBU at room temperature (3 min). Further reaction (10 h) of 7i with DBU provided the isomerically pure (>99%) 8 as confirmed by HPLC analysis. Coupling constants of the olefinic protons (J = 15 Hz) indicated the compound was in the E configuration.

The C-10-benzylated anthralin derivatives (9a–c and 10) were prepared as outlined in Scheme III. The synthesis of the monobenzylated compounds 9a–c was accomplished by reaction of anthralin with the corresponding benzyl halides in the presence of potassium carbonate in acetonitrile.
The dibenzylated 10 was obtained in an analogous manner using the requisite molar ratio of benzyl chloride.

**Biological Evaluation**

**Inhibition of 5-Lipoxygenase**. The anthrone derivatives were evaluated for their ability to inhibit the production of LTB4 and 5-HETE in isolated bovine polymorphonuclear leukocytes (PMNL). 37,38 Leukotriene biosynthesis was initiated with Ca ionophore A23187. LTB4 and 5-HETE concentrations were measured by reversed-phase HPLC with UV detection. Table I summarizes the inhibitory properties of the new compounds as expressed by their IC50 values. Several compounds in our series had IC50 values ranging between 0.3 and 0.6 μM and were far more potent than anthralin (37 μM in this test). Data for known antipsoriatic anthrones, the standard 5-LO inhibitor nordihydroguaiaretic acid (NDGA) and lonapalene, a 5-LO inhibitor that showed clinical efficacy as an antipsoriatic agent, are given in Table II. The effect of anthralin itself on arachidonic acid lipoxygenation was previously reported. In human neutrophils and bovine neutrophils, it inhibits the production of LTB4 with IC50 values.

**Notes**:

- a Inhibition of 5-HETE and LTB₄ biosynthesis in bovine PMNL. Inhibition was significantly different with respect to that of the control, P < 0.01. Values in parentheses are percent inhibition at the indicated concentrations (μM), and standard errors average 10% of the indicated values.
- b Reducing activity against 2,2-diphenyl-1-picrylhydrazyl with an equimolar amount of the test compound. Not reactive; kDPPH < 1 M⁻¹ s⁻¹. Highly reactive (approximate values).
- c Deoxyribose-damaging property as a measure of hydroxy radical formation. Indicated values are μmol of malondialdehyde/μmol of deoxyribose released by 75 μM test compound (controls <0.1). Values are significantly different with respect to the control, P < 0.01.
- d Inhibition of lipid peroxidation in bovine brain phospholipid liposomes; n = 3 or more.
- e Values are significantly different with respect to anthralin, P < 0.01.
- f Not determined.

* The dibenzylated 10 was obtained in an analogous manner using the requisite molar ratio of benzyl chloride.
The mere presence of an acyl substituent at C-10 of the corresponding saturated chain compound (4h). This demonstrates that a terminal aromatic ring is required. 4h and 4p, those obtained for the w-phenyl derivatives was markedly less active than in the linking chain three carbons. Activity was observed when the length of the chain was further increased to four carbons (4q). In addition, a beneficial effect of inserting methylene groups between the C-10 carbonyl group and the phenyl rest. Optimal activity was observed with the unsubstituted derivative (4t). That of the unsubstituted derivative was notably less active than in the 4-position of the terminal aromatic ring. 4c consistently high activity. Introduction of ether groups in the beneficial effect. The triacetoxyanthracene and butantrone, which had been in clinical trials for the treatment of psoriasis, are only moderate inhibitors.

Structure–activity studies showed that in general the 10-phenylacyl-substituted analogs 4a–u were more effective than the C-10 phenylalkylidene derivatives 7a–r. The 10-phenylalkyl- or 10,10-bis(phenylalkyl)-substituted compounds 6a–m, 8, 9a–c, and 10 were without appreciable effect (data not shown).

The 10-phenylacyl-substituted derivatives showed consistently high activity. Introduction of ether groups in the 4-position of the aromatic ring (4e and 4d) strongly increased activity as compared to 4a, although the di- and triacetoxyanthracene 9a and 9c were notably less active or inactive, respectively, probably on account of high lipophilicity and limited solubility in the test system. The presence of free phenolic groups did not necessarily lead to improved efficacy in inhibiting 5-LO as compared to nonphenolic compounds. Only if the terminal aromatic ring was substituted by three phenolic groups (4t) was inhibitory action significantly improved as compared to that of the unsubstituted derivative 4a. Furthermore, the inhibitory effects increased with the length of the acyl chain linking the anthrone nucleus and the phenyl ring terminus. Compounds 4a, 4h, 4p, and 4q demonstrate the beneficial effect of inserting methylene groups between the C-10 carboxyl group and the phenyl rest. Optimal activity was observed when the length of the chain was three carbons (4p). A derivative with a trans double bond in the linking chain (4m) was markedly less active than the corresponding saturated chain compound (4h). Comparison of the IC50 value obtained for butantrone (3) with those obtained for the w-phenyl derivatives 4h and 4p, where the 10-butyryl substituent is replaced by a phenylpropionyl or phenylbutyryl group, respectively, clearly demonstrates that a terminal aromatic ring is required. The mere presence of an acyl substituent at C-10 of anthralin does not necessarily lead to enhanced 5-LO inhibitory activity.

In the 10-phenylalkylidene series, with the exception of the 4-nitro derivative 7d and the compound 7j, compounds which lack free hydroxy groups in the attached phenyl ring were only moderate inhibitors, whereas the phenolic analogs 7p–r strongly inhibited LTB4 formation. The effect of chain length on activity was less pronounced in the phenylalkylidene series; however, the phenylpropylidene chain was optimal for compounds terminated with an unsubstituted phenyl rest (7j).

Finally, substitution of one or both protons at C-10 of anthralin by benzyl groups (9a–c and 10) abolished 5-LO inhibition, in accordance with the findings that 10-monodialkylation of anthralin results in loss of antiinflammatory activity.40,41 To rule out apparent inhibition due to nonspecific toxic effects of the potent derivatives, the treated PMNL were checked for viability using the trypan blue exclusion test. Cell viability was always greater than 80%.

Since the use of intact cells requires penetration of the test compound into the cell, control experiments were performed using an homogenate of bovine PMNL which was obtained by sonification of the cell suspension.42 The two highly effective compounds 4p and 4t and the less effective compounds 4f and 7b were tested at both 3 and 30 μM. However, LTB4 synthesis was inhibited with comparable potency whether it was determined in whole cells or under cell-free conditions. Thus, there is no barrier to penetration of the compounds. In addition, this demonstrates that the compounds act directly on 5-LO. Effects on other targets, e.g., 5-LO-activating protein,43 can be excluded.

Lipophilicity. In some studies on 5-LO inhibitors, relationships between the log of the octanol/water partition coefficients (log P) and the structural changes resulting in increased activity were reported.25,26,44 Thus, as a measure of lipophilicity, we determined the log P values of the new compounds by a standard HPLC procedure.45 In our case, there was no clear relationship found between 5-LO inhibition and lipophilicity. The compounds exhibited a wide range of log P values (2.61–5.67, Table III). In general, changes in lipophilicity were well tolerated. Compound 4t as the most hydrophilic representative as well as the lipophilic 4d exhibited high activity. The most lipophilic representative with acceptable activity was 7j, although solubility limited the assay concentrations of compounds with greater lipophilicity.

Antioxidant Determination. Because conversion of arachidonic acid into LTB4 by 5-LO is a radical-based oxidation, it is not surprising that most 5-LO inhibitors possess redox properties and can be considered as antioxidants/free-radical scavengers.43 These compounds inhibit 5-LO by donating an electron during enzyme catalysis. Because a radical-scavenging antioxidant reacts rapidly with the stable free radical DPPH,46,47 we determined the reactivities of the new compounds with DPPH by the decrease in absorbance at 516 nm (Table I). Phenyacyl substitution at C-10 of anthralin substantially reduced reactivity with DPPH as compared to that of anthralin (Table II), whereas substitution of both C-10

\end{align*}
\]
hydrogen atoms of anthralin by phenylalkylidene groups nearly abolished reactivity with DPPH. On the other hand, substitution on the phenyl moiety of the side chain by two or three hydroxy groups (4s, 4t, 7q, and 7r) dramatically increased redox activity, reflecting the reducing capability of the phenolic hydroxyl. Similar reducing effects were observed for the cinnamoyl derivatives 4m-o and the 2,6-di-tert-butylphenol derivative 4g. The reactivity of compound 7p which has only one phenolic group is explained by increased resonance stabilization of the corresponding radical.

**Hydroxy-Radical Production.** Further studies on the redox behavior of the new compounds have been performed using the deoxyribose assay, which is a sensitive test for the production of hydroxyl radicals. The release of thiobarbituric-acid-reactive material (expressed as malondialdehyde, MDA) is a measure for hydroxyl-radical formation and thus reflects prooxidant properties of the compounds.\(^\text{49,50}\) The data obtained from this test (Table I) demonstrate that with the exception of the C-10 cinnamoyl anthralin derivatives (4m-o) and the compounds with free phenolic groups in the C-10 substituent (4s-u, 7q, and 7r), the formation of hydroxyl radicals was substantially reduced with respect to anthralin (Table II). The phenylalkyl substituted compounds 8, 9a-c, and 10 did not produce hydroxyl radicals (data not shown). The catechol 4s and the pyrogallol derivative 7r led to the release of even larger amounts of MDA than did anthralin (Table II), indicating enhanced formation of hydroxyl radicals. Furthermore, there is no direct relationship between 5-LO inhibitory potency and formation of hydroxyl radicals by 1,8-dihydroxy-9(10H)-anthracenones.

**Inhibition of Lipid Peroxidation.** The inhibitory effect on lipid peroxidation of some representative compounds was evaluated with bovine brain phospholipid liposomes which provide an ideal model system for lipid peroxidation studies.\(^\text{51}\) Lipid peroxidation was stimulated with Fe\(^{2+}\)/ascorbic acid.\(^\text{49}\) The 10-phenylacylated compounds tested gave IC\(_{50}\) values of 1-2 \(\mu\)M (Table I), being significantly more efficient than anthralin (12 \(\mu\)M).\(^\text{19}\) Thus, the variation of the phenylacyl substituent while leading to significant changes in 5-LO inhibitory activity can maintain high activity in inhibition of lipid peroxidation. Surprisingly, even compounds that were not reactive with DPPH did not generate hydroxyl radicals did show activity in this test (e.g., 4s and 7j). For comparison, the compounds 6a and 10 were without appreciable effect (IC\(_{50}\) > 50, data not shown).

**Discussion**

Our results show that the 1,8-dihydroxy-9(10H)-anthracenone nucleus, although not a potent inhibitor of 5-LO in itself, can provide a useful template for the design of potent inhibitors of leukotriene biosynthesis. Moreover, the results support our hypothesis that structural modification of anthralin may lead to control of the release of active oxygen species, as determined by the potency of the compounds to generate hydroxyl radicals. Although 5-LO inhibitory action of 1,8-dihydroxy-9(10H)-anthracenones was not proportionally related to the generation of hydroxyl radicals, compounds which were potent generators of hydroxyl radicals were also effective in 5-LO inhibition (4i, 4s-u, and 7r). Furthermore, those compounds that were substituted by phenylalkyl groups (8, 9a-c, and 10) at C-10, which resulted in the loss of hydroxyl-radical formation, were inactive. On the other hand, decreasing or abolishing the potency of hydroxyl-radical formation by incorporation of a 10-phenylacyl or 10-phenylalkylidene substituent did not necessarily reduce 5-LO inhibition.

Many 5-LO inhibitors inhibit lipid peroxidation,\(^\text{53,54}\) and it is believed that 5-LO inhibition by those substances is due to scavenging of intermediate radicals that are formed within the active site of the enzyme. The most potent 5-LO inhibitors of our series were all effective inhibitors of lipid peroxidation in model membranes. However, examination of the reactivities of the compounds against DPPH in Table I shows the lack of correlation between the ability to intercept a free radical and 5-LO inhibitory potency, suggesting that a simple antioxidant effect does not explain the activity of several inhibitors. The inhibitory effects of these compounds appear to be due to specific enzyme interaction rather than nonspecific redox properties.

The anthralin anion (1a) is the key intermediate in the oxidation process, which involves a one-electron transfer from the anion to oxygen to give the anthralin-10-yl free radical and the active oxygen species.\(^\text{14}\) 5-LO contains a non-heme iron that is converted to the ferric form upon activation.\(^\text{55}\) Thus, it may be expected that similar to the oxidation process, electron transfer from the anthralin anion to the active ferric form of 5-LO results in an inactivated enzyme (ferrous form), according to a proposed mechanism.\(^\text{56}\) The so-called redox-active inhibitors are supposed to exert their action by this mechanism.\(^\text{57}\) In addition to the redox properties, other factors such as an appropriate geometry of the molecules when bound to the active site of the enzyme may be responsible for the 5-LO inhibitory activities of the novel anthralin analogs. This is supported by the fact that for these compounds, a definite length of the chain linking the anthrone nucleus and the phenyl rest was optimal for activity.

It has been suggested that the generation of active oxygen species by anthralin is responsible for the inflammation of uninvolved skin.\(^\text{17}\) Hence, inhibitors which lack hydroxy-radical formation may be expected to be devoid of skin-irritating properties. Furthermore, redox inhibitors are oxidized during their action on LO.\(^\text{58}\) Consequently, their stability is limited.\(^\text{59}\) Indeed, HPLC analysis of the incubation mixtures at the end of the 5-LO assay revealed that anthralin was almost completely degraded to its dimer bianthrone and the corresponding anthraquinone, danthron. Both metabolites are not effective in 5-LO inhibition, among which were more powerful generators of hydroxyl radicals than anthralin, while some compounds maintained 5-LO inhibitory potency but did not generate hydroxyl radicals. Several compounds are being evaluated as potential antipsoriatic agents devoid of inflammatory and staining effects.
prepared from the corresponding acids by chromatography to afford yellow crystals (Table III): *H NMR (DMSO-d6) δ 11.89 (s, 2H), 7.87 (t, 3H), 7.61-7.53 (m, 6H), 6.00 (s, 2H), 5.70 (s, 1H), 3.73 (s, 3H), 3.54-3.30 (m, 8H), 1.40-1.10 (m, 2H), FTIR 1631 cm⁻¹ (CO-HO); MS m/z 574 (M⁺). Preparation of α-Chloro Methyl Ethers 5a–m. The appropriate aldehydes were converted to the corresponding dimethyl acetics and then to the α-chloro methyl ethers according to literature procedures.⁶,⁷

General Procedure for the Preparation of 1,8-Dihydroxy-10-(1-methoxy-ω-phenylalkyl)-9(10H)-anthracenones 7a–h and 7j–m. A suspension of 6i (0.5 g, 1.39 mmol) in absolute ethanol (10 mL) was treated with DBU (1.1 g, 7.23 mmol). The reaction mixture was stirred at room temperature for compounds 4b, 4d, 4e–g, and 4m, cooled, and filtered, and the filtrate was evaporated. The residue was purified by chromatography. Recrystallization from absolute alcohol afforded yellow crystals (Table IV): ¹H NMR (CDCl₃) δ 12.22 (s, 1H), 12.20 (s, 1H), 7.60–6.75 (m, 11H), 4.45 (d, 1H, J = 4 Hz), 3.45 (s, 3H), 3.40–3.25 (m, 1H), 2.65–2.25 (m, 2H), 1.40–1.10 (m, 2H), FTIR 1631 cm⁻¹ (CO-HO); MS m/z 574 (M⁺). Anal. (C₁₇H₁₅NO₆): C, H.

1,8-Dihydroxy-10-(2-phenylethylidene)-9(10H)-anthracene (7l). A suspension of 6i (0.5 g, 1.39 mmol) in absolute methanol (10 mL) was treated with DBU (1.1 g, 7.23 mmol). The reaction mixture was then stirred for 3 min by the addition of excess N HCL. The reaction mixture was shaken thoroughly and extracted with CH₂Cl₂. The combined extracts were washed with saturated aqueous NaCl, dried over Na₂SO₄, and evaporated. The residue was purified by chromatography to afford 7i as yellow crystals (Table III, 97% isomerically pure by HPLC analysis with respect to 8): ¹H NMR (CDCl₃) δ 12.26 (s, 1H), 12.20 (s, 1H), 7.60–6.75 (m, 11H), 4.45 (d, 1H, J = 7.4 Hz), 3.95 (d, 2H, J = 7.4 Hz), FTIR 1630 cm⁻¹ (CO-HO); MS m/z 528 (M⁺). Anal. (C₂₁H₁₄NO₆): C, H.

General Procedure for the Preparation of 1,8-Dihydroxy-10-(ω-phenylalkylidene)-9(10H)-anthracene (7). A solution of 6j (0.5 g, 1.33 mmol) in pyridine (10 mL) was refluxed under N₂ for 15–30 min until the reaction was completed (TLC control). The reaction mixture was then cooled and poured into water (200 mL), acidified with 6 N HCL, and extracted with CH₂Cl₂. The combined CH₂Cl₂ extracts were washed with saturated aqueous NaCl, dried over Na₂SO₄, and then evaporated. The residue was purified by chromatography to afford 7a as yellow crystals (Table III, 97% isomerically pure by HPLC analysis with respect to 8): ¹H NMR (CDCl₃) δ 12.26 (s, 1H), 12.20 (s, 1H), 7.65–6.90 (m, 11H), 6.50 (t, 1H, J = 7.4 Hz), 3.95 (d, 2H, J = 7.4 Hz), FTIR 1630 cm⁻¹ (CO-HO); MS m/z 528 (M⁺). Anal. (C₂₁H₁₄NO₆): C, H.

10-[(4-Carboxyphenyl)methylen] 1,8-dihydroxy-9(10H)-anthracene (7a). A suspension of 6e (0.5 g, 1.47 mmol) in 50% sulfuric acid (40 mL) and glacial acetic acid (40 mL) was refluxed for 24 h. The reaction mixture was cooled in an ice bath, and the resulting crystals were filtered by suction and washed thoroughly with water, then with a small amount of cold.

**Experimental Section**

Melting points were determined with a Büchi 510 melting point apparatus and are uncorrected. Chromatography refers to column chromatography on silica gel (E. Merck, 70–230 mesh). In most cases, the concentrated crude products obtained by chromatography using the indicated eluents (Tables III and IV) were treated with a small amount of hexane to induce precipitation. ¹H NMR spectra were recorded with a Varian EM 390 spectrometer, (70 eV). HPLC apparatus and are uncorrected. Chromatography refers to the higher-order procedure.

**Preparation of Acyl Chlorides.** Acyl chlorides were prepared from the corresponding acids by the following standard procedures.⁶,⁷ In most cases, the crude products were used in the subsequent acylation steps.
methanol, and then with petroleum ether (40–60 ºC) to afford a yellow powder (Table III): 1H NMR (DMSO-d6) δ 12.10 (s, 1H), 12.00 (s, 1H), 7.95–6.85 (m, 11H); FTIR 1618 (COOH), 1630 cm⁻¹ (CO–HO); MS m/z 372 (80). Anal. (C₁₇H₂₀O₄): C, H.

1,8-Dihydroxy-10-[4-(methoxycarbonyl)phenylmethylene]-9(10H)-anthracenone (7a)

A suspension of 7a (0.5 g, 1.45 mmol) in absolute methanol (180 mL) and 96% sulfuric acid (0.5 mL) was refluxed for 24 h. The reaction mixture was cooled to 20 ºC, and the resulting crystals were filtered by suction. Purification by chromatography gave orange-yellow crystals (Table III): 1H NMR (CDCl₃) δ 12.30 (s, 1H), 12.20 (s, 1H), 8.10–6.90 (m, 11H), 7.35 (s, 2H); FTIR 1717 (CO₂H), 1650 cm⁻¹ (CO–HO); MS m/z 372 (80). Anal. (C₁₇H₁₉O₅): C, H.

General Procedure for the Cleavage of Methyl Ethers

7p–r. 1,8-Dihydroxy-10-[4-(hydroxyphenyl)methylene]-9(10H)-anthracenone (7p). A solution of 7f (0.5 g, 1.45 mmol) in dry CH₂Cl₂ (10 mL) was added dropwise to a solution of BBr₃ (0.5 g, 1.45 mmol) in CH₂Cl₂ (20 mL) at 0 ºC under N₂. The mixture was left to warm to room temperature and stirred for 24 h. Excess water was added, and the mixture was extracted with ether. The ether phase was dried and evaporated and the residue purified by chromatography to afford 7p as orange-red crystals (Table III): 1H NMR (DMSO-d₆) δ 12.15 (s, 1H), 12.00 (s, 1H), 9.80 (s, 1H), 7.70–6.60 (m, 11H); FTIR 3423 (OH), 1650 cm⁻¹ (CO–HO); MS m/z 372 (80). Anal. (C₁₇H₁₉O₅): C, H.

(E)-1,8-Dihydroxy-10-(2-phenylethenyl)-9(10H)-anthracene (8a). A suspension of 6i (0.5 g, 1.39 mmol) in absolute methanol (10 mL) was treated with DBU (1.2 g, 7.23 mmol). The mixture was stirred at room temperature for 10 h, under N₂ and protected from light, until the reaction was completed by TLC analysis on silica gel RP-18, methanol/water/acidic acid (9:1–0.1). The reaction mixture was shaken thoroughly with excess 2 N HCl and extracted with CH₂Cl₂. The organic phase was dried over Na₂SO₄ and then evaporated. The residue was purified by chromatography to afford 8 as yellow crystals (Table IV, δ 6%, >99% isomerically pure by HPLC analysis with respect to 7i): 1H NMR (CDCl₃) δ 12.30 (s, 2H), 7.55–6.85 (m, 11H), 6.59 (d, 1H, J = 15 Hz), 6.06 (dd, 1H, J = 1/2 Hz), 4.90 (d, 1H, J = 9 Hz); FTIR 1632 cm⁻¹ (CO–HO); MS m/z 328 (99). Anal. (C₁₇H₁₇O₃): C, H.

General Procedure for the Preparation of 1,8-Dihydroxy-10-(ω-phenylalkyl)-9(10H)-anthracenes 9a–c, 1,8-Dihydroxy-10-(phenylmethyl)-9(10H)-anthracene (9a).

Anthrinal (1 g, 4.42 mmol) and dry NaN₃ (1.25 g) were suspended in absolute acetone (60 mL) under N₂. Benzyl chloride (0.62 g, 4.90 mmol) and catalytic amounts of potassium iodide were added, and the mixture was refluxed for 15 h under N₂. Then the mixture was cooled, treated with water and 2 N sulfuric acid, and extracted exhaustively with CH₂Cl₂. The combined organic extracts were washed with water, dried over Na₂SO₄, and then evaporated. The residue was purified by chromatography to afford 9a as yellow crystals (Table IV): 1H NMR (CDCl₃) δ 11.95 (s, 2H), 7.50–6.30 (m, 11H), 4.45 (t, 1H, J = 6 Hz), 3.05 (d, 2H, J = 6 Hz); FTIR 1634 cm⁻¹ (CO–HO); MS m/z 316 (24). Anal. (C₁₇H₁₉O₃): C, H.

1,8-Dihydroxy-10,10-bis(benzylnethyl)-9(10H)-anthracene (10). A 10% suspension of 9a (1 g, 2.84 mmol) in benzyl chloride (2.5 g, 22.12 mmol), and dry NaN₃ (6 g) as described for 9a, but the reflux was maintained for 6 h. 10 was obtained as yellow crystals (Table IV): 1H NMR (CDCl₃) δ 12.30 (s, 2H), 7.75–6.30 (m, 16H), 3.65 (s, 4H); FTIR 1638 cm⁻¹ (CO–HO); MS m/z 406 (22). Anal. (C₁₇H₂₃O₃): C, H.

log P Determination. The method is based on the linear relationship between the capacity factors log k' of the compounds and their log P values. The log k' values of five compounds (4-nitrophenol, 4-chlorophenol, benzophenone, naphthalene, and anthracene) with known log P values (1.91, 2.39, 3.18, 3.44, and 4.49, respectively) were determined. A plot of log k' versus log P generated from this calibration mixture was used for the calculation of log P values for unknowns from the logarithms of their chromatographic capacity factors (correlation coefficient > 0.99; n = 3). Methanol/water/acetic acid (77:23:0.1), adjusted to pH 5.5 with concentrated NH₄OH, was used as eluant.

Determination of the Reducing Activity against 2,2'-Diphenyl-1-picrylhydrazyl. To a solution (10⁻⁴ M) was added 1 mL of DPPH solution (10⁻⁴ M), each in acetone/PBS (1:1 v/v), and the reduction of DPPH was followed spectrophotometrically at 516 nm. Plots of the reciprocal of DPPH concentrations against time gave straight lines, and the second-order rate constants were obtained from the slopes and are expressed as mean values (n = 3–6).

Degradation of 2-Deoxy-d-ribose. The following reagents were added to glass tubes in the order and at the final concentrations stated: 0.3 mL of KH₂PO₄/KOH buffer, pH 7.4 (3:1 v/v), 0.2 mL of H₂O (double distilled), 0.2 mL of 2-deoxy-d-ribose (2 mM), 0.2 mL of FeCl₃·6H₂O (0.1 mM), and 0.1 mL of anthracene derivative (75 μM). Stock solutions of the compounds were made up fresh before use. Appropriate blanks and controls with the vehicle (acetonitrile) were conducted. The reaction mixtures were incubated for 2 h at 37 ºC in a shaking water bath. Trichloroacetic acid (1.0 mL, 2.5% w/v) and 1.0 mL
of 1% (w/v in 0.05 N NaOH) 2-thiobarbituric acid (TBA) were added, and the samples were heated at 100 °C for 15 min and then cooled in an ice bath (5 min). Then, 2.0 mL of the reaction mixtures was treated with 0.05 mL of 36% (w/v) HCl and 2.0 mL of 1% HCl solution, and the mixtures were vigorously shaken in a vortex mixer (Heidolph) for 15 s. The mixture was separated by centrifugation at 1500g (15 min), and the absorbance at 532 nm was measured against butanol. Calibration was performed using a malondialdehyde standard prepared by hydrolysis of 1,1,3,3-tetraethoxypropane. TBA-reactive material is expressed in terms of amol of MDA/mmol deoxyribose.

Assay of Lipid Peroxidation in Bovine Brain Phospholipid Liposomes. Bovine brain phospholipids were prepared essentially as described by Gutteridge.16 They were weighed into glass tubes and mixed in a vapo (Heidolph) with the presence of five small glass beads (d. o. 4 mm) for 1 min. The phospholipids were suspended in 0.15 M NaCl, pH 7.4, to a final concentration of 5 mg/mL. The mixture was purged with N2 for 1 min and vigorously dispersed in a vortex mixer for 5 min. The liposomes were allowed to swell for 1 h at 4 °C.

The following reagents were added to glass tubes in the order and at the final concentrations stated: 0.3 mL of KH2PO4-KOH buffer, pH 7.4 (30 mM), 0.19 mL of H2O (double distilled), 0.2 mL of liposomes (1 mg/mL), 0.2 mL of FeCl3·6H2O (0.1 mM), 0.1 mL of a 1% thioridazine, 1 mM of an antioxidant (variable concentrations). Appropriate blanks and controls with the vehicles (acetone) were conducted. The reaction mixtures were incubated for 1 h at 37 °C in a shaking water bath. BHT (10 μL, 20% w/v), 0.5 mL of 25% (w/v) HCl, and 0.5 mL of 1% 2-thiobarbituric acid were added, and TBA-reactive material was measured as described above.

Bovine PMNL 5-Lipoygenase Assay. PMNL were prepared essentially as described from sodium EDTA-anticoagulated bovine blood Contaminating platelets were removed by repeated centrifugations at 100g for 30 min. The purified PMNL were suspended in 1 mL of 100 mM HEPES (pH 7.4) containing 130 mM NaCl, 1.5 mM MgCl2, and 0.5 mM CaCl2. PMNL were prepared as described. Preincubation was performed with 2.4 mL of the suspension and 6 μL of 1% (w/v in 0.05 N NaOH) 2-thiobarbituric acid (TBA) were added, and TBA-reactive material was measured as described above.

The 50% inhibition point. Degradation of anthralin, 4p, and 7j under test conditions: The incubation mixture was diluted with 10 mL of water and passed through an octadecylamine reversed-phase cartridge (Baker). After elution with 2×5 mL of water, the compounds were eluted with 3×1 mL of methanol and subjected to reversed-phase HPLC analysis. The isocratic elution conditions were methanol/water/acetic acid (85–15–0.1), 254 nm. The concentrations of the compounds and the metabolites biotransformed and danthron were determined from comparison of the corresponding peak area with known amounts of standards.

Acknowledgment. We thank Mrs. C. Braun and Mr. K. Ziereis for their excellent technical assistance, Dr. K. K. Mayer for the mass spectral measurement, Mr. G. Wandinger for the elemental analyses, and Prof. Dr. G. Wurm, Berlin, for a gift of lonapalene. D.G. thanks the Schlosser-Stiftung for a scholarship.
