Activation of NADPH oxidase by purine and pyrimidine nucleotides involves G proteins and is potentiated by chemotactic peptides

INTRODUCTION

Human neutrophils and HL-60 leukaemic cells possess an NADPH oxidase which catalyses superoxide (O$_2^-$) formation and is activated by the chemotactic peptide, N-formyl-l-methionyl-l-leucyl-l-phenylalanine (fMet-Leu-Phe). In dibutyryl cyclic AMP-differentiated HL-60 cells, ATP and UTP in the presence of cytochalasin B activated O$_2^-$ formation with EC$_{50}$ values of 5 µM and efficacies amounting to 30% of that of fMet-Leu-Phe. The potency order of purine nucleotides in activating O$_2^-$ generation was ATP = adenosine 5'-O-(3-thiotriphosphate) > ITP > dATP = ADP. Pyrimidine nucleotides activated NADPH oxidase in the potency order UTP > dUTP > CTP = TTP = UDP. Pertussis toxin completely prevented activation of NADPH oxidase by fMet-Leu-Phe and UTP, whereas the effect of ATP was only partially inhibited. ATP and UTP enhanced O$_2^-$ generation induced by fMet-Leu-Phe by up to 8-fold, and primed the cells to respond to non-stimulatory concentrations of fMet-Leu-Phe. Activation of NADPH oxidase by UTP but not by ATP was inhibited by various activators of adenylyl cyclase. In dimethyl sulphoxide-differentiated HL-60 cells and in human neutrophils, ATP and UTP per se did not activate NADPH oxidase, but they potentiated the effect of fMet-Leu-Phe. Our results suggest that purine and pyrimidine nucleotides act via purino- and novel pyrimidinoceptors respectively, which are coupled to guanine nucleotide-binding proteins leading to the activation of NADPH oxidase. As ATP and UTP are released from cells under physiological and pathological conditions, these nucleotides may play roles as intercellular signal molecules in the activation of O$_2^-$ formation.

Human neutrophils and HL-60 leukaemic cells possess an NADPH oxidase which catalyses superoxide (O$_2^-$) generation and is activated by the chemotactic peptide, N-formyl-l-methionyl-l-leucyl-l-phenylalanine (fMet-Leu-Phe) (McPhail & Snyderman, 1984; Rossi, 1986). Formyl peptide receptors interact with guanine nucleotide-binding proteins (G proteins) leading to the activation of phospholipase C, which catalyses the degradation of polyphosphoinositides to inositol phosphates and diacylglycerol (Lad et al., 1985a; Ohta et al., 1985). ADP-ribosylation of the G proteins by pertussis toxin prevents cell activation (Lad et al., 1985a; Ohta et al., 1985; Gierschik et al., 1987; Gilman, 1987). The mechanism by which chemotactic peptides activate NADPH oxidase has been suggested to involve protein kinase C, as cell-permeable diacylglycerol and phorbol myristate acetate are stimulators of protein kinase C and of O$_2^-$ generation (McPhail & Snyderman, 1984; Rossi, 1986). However, we and others have recently provided evidence that activation of NADPH oxidase involves more direct regulation by G proteins (Seifert et al., 1986, 1988; Seifert & Schultz, 1987a,b; Gabig et al., 1987).

Under physiological and pathological conditions, nucleoside triphosphates are released into the extracellular space from a variety of cell types (Goetz et al., 1971; Shirasawa et al., 1983; Gordon, 1986; Hardebo et al., 1987; Forsberg et al., 1987). Released ATP binds to purinoceptors which regulate many cell functions (Burnstock & Kennedy, 1985; Gordon, 1986). Purinoceptors can be classified into subtypes according to the potency of purinergic agonists. Recently, ATP was reported to activate phospholipase C in HL-60 cells (Dubyak et al., 1987). In addition, ATP induces an increase in the intracellular Ca$^{2+}$ concentration in human neutrophils and enhances fMet-Leu-Phe-induced O$_2^-$ formation (Kuhns et al., 1988). Not only ATP but also UTP plays a role as modulator of cellular functions (Mustard & Packham, 1970; Shirasawa et al., 1983; Dubyak & DeYoung, 1985; Forsberg et al., 1987; Hardebo et al., 1987; Kügelen et al., 1987; Häussinger et al., 1987). There is recent evidence that UTP does not mediate its effects via purinoceptors (Kügelen et al., 1987; Häussinger et al., 1987). These findings prompted us to study the role of purine and pyrimidine nucleotides in the regulation of NADPH oxidase. We report here that ATP and UTP act on purino- and putative pyrimidinoceptors in HL-60 cells and in human neutrophils to activate NADPH oxidase via G proteins.

MATERIALS AND METHODS

Materials

N-t-Butoxycarbonyl-l-phenylalanyl-l-leucyl-l-phenylalanyl-l-leucyl-l-phenylalanine, prostaglandin E$_2$, isoproterenol, cholera toxin, 5'-N-ethylcarboxamidoadenosine, α,β-methylene-ATP, uridine, uridy(3'5')-
uridine, PP, and TTP were obtained from Sigma Chemie (Deisenhofen, Germany). All other nucleotides were from Boehringer Mannheim (Mannheim, Germany). Pertussis toxin was kindly provided by Dr Motuyuki Yajima (Kyoto, Japan). Sources of other materials and cell culture media have been described elsewhere (Seifert et al., 1986, 1988; Seifert & Schultz, 1987a, b; Seifert & Schächtele, 1988).

Cell culture
HL-60 cells were grown in suspension culture in RPMI-1640 medium supplemented with 10% (v/v) horse serum, 1% (v/v) non-essential amino acids, 2 mm-L-glutamine, 50 U of penicillin/ml and 50 μg of streptomycin/ml in a humidified atmosphere with 7% CO₂ at 37 °C. To induce differentiation, cells were seeded at a density of 10⁶/ml and were cultured for 48 h in the presence of 0.2 mm-dibutyryl cyclic AMP or for 120 h in the presence of 160 mm-dimethyl sulfoxide (Chaplinski & Niedel, 1982; Seifert & Schächtele, 1988). Cells were harvested by centrifugation for 10 min at 250 g. Wright–Giemsa-stained smears showed that > 95% of the cells were myelocytes or cells beyond this stage.

Preparation of human neutrophils
Heparinized blood was obtained by venous puncture from healthy volunteers of either sex who had taken no drugs for at least 3 weeks. Neutrophils were isolated by dextran sedimentation and centrifugation through Ficoll-Hypaque (Seifert & Schultz, 1987a). Cells preparations contained more than 98% viable neutrophils as judged by Trypan Blue dye exclusion.

Assay for O₂⁻ generation
NADPH oxidase-catalysed O₂⁻ generation was monitored by continuous measurement of ferricytochrome C reduction inhabitable by superoxide dismutase, using a Uvikon 810 dual-beam spectrophotometer (Kontron, Eching, Germany). Reaction mixtures (1 ml) contained 5 x 10⁶ HL-60 cells or 2 x 10⁶ neutrophils, 100 μm-ferricytochrome C and a buffer consisting of: 138 mM-NaCl, 6 mM-KCl, 1 mM-MgCl₂, 1 mM-CaCl₂, 1 mM-NaHPO₄, 5 mM-NaHCO₃, 5.5 mM-glucose and 20 mM-Hepes, pH 7.4. Unless stated otherwise, all assays were performed in the presence of cytochalasin B (1 μg/ml). Reaction mixtures were preincubated at 37 °C for 3 min. O₂⁻ generation was initiated by the addition of the stimulus. The Vₘₐₙₐₜ of O₂⁻ generation was calculated from the linear sections of absorbance curves (Seifert & Schächtele, 1988).

RESULTS
The effects of various purine nucleotides on NADPH oxidase were studied in HL-60 cells differentiated with dibutyryl cyclic AMP (Fig. 1). In the presence of cytochalasin B, ATP activated NADPH oxidase with an EC₅₀ of 5 μM and a maximum at 100 μM. The structure of the polyphosphate chain of adenine nucleotides was critical, as adenosine 5'-O-(1-thiotriphosphate), adenylyl imidodiphosphate, α,β-methylene-ATP and β,γ-methylene-ATP did not activate NADPH oxidase at concentrations up to 100 μM (results not shown). In contrast, adenosine 5'-O-(3-thiotriphosphate) was as potent as ATP. The length of the phosphate chain and the substitution of the ribose moiety were also of importance, as ADP and dATP were far less potent and efficient than ATP. P₃, PP₃, AMP and adenosine did not activate NADPH oxidase at concentrations up to 100 μM (results not shown). Furthermore, NADPH oxidase activation by pyrimidine nucleotides exhibited base specificity. ATP was less potent than ATP, and activated O₂⁻ generation with an efficacy amounting to 60% of that of ATP. GTP, β,γ-methylene-GTP, guanosine 5'-O-(3-thiotriphosphate)

![Fig. 1. Activation of NADPH oxidase by purine and pyrimidine nucleotides in HL-60 cells differentiated with dibutyryl cyclic AMP](image-url)

(a) Concentration–response curves to purine nucleotides: ○. ATP; □, adenosine 5'-O-(3-thiotriphosphate); ▲. dATP; ▼, ADP; □, ITP. (b) Concentration–response curves to pyrimidine nucleotides: ○, UTP; ▲, dUTP; ▼, UDP; △, TTP; □, CTP. The open circles indicate that nucleotides at the indicated concentrations did not activate O₂⁻ formation. Nucleotides did not affect cell viability as measured by Trypan Blue dye exclusion and release of lactate dehydrogenase. Data shown represent the means of duplicate assays obtained with one preparation of HL-60 cells, which varied by less than 5%. The variation in O₂⁻ generation rates in ten experiments carried out with different batches of HL-60 cells was less than 10%.
and guanylyl imidodiphosphate at concentrations up to 100 μM were inactive (results not shown). Among the pyrimidine nucleotides, UTP activated NADPH oxidase with a potency and an efficacy comparable to that of ATP. dUTP, TTP, CTP and UDP were far less potent and efficient activators of NADPH oxidase than was UTP. UMP, uridine, uridy1(3′-5′)uridine and UDP-glucose were inactive at concentrations up to 100 μM (results not shown). Recently, αβ-methylene-ATP has been reported to be a partial antagonist at certain purinoceptors (Katsuragi & Furukawa, 1985). However, αβ-methylene-ATP at a concentration of 100 μM did not prevent activation of O₂⁻ formation by ATP or UTP at a concentration of 10 μM (results not shown). Similar results as with αβ-methylene-ATP were obtained with AMP and UMP.

Some characteristics of NADPH oxidase activation by UTP, ATP and fMet-Leu-Phe were compared (Fig. 2). The efficacies of maximally stimulatory concentrations of ATP and UTP to activate O₂⁻ generation amounted to 30–50% of that of a maximally effective concentration of fMet-Leu-Phe, with respect both to Vₘₐₓ and to the absolute amount of O₂⁻ generated. In addition, nucleotides and chemotactic peptides reversibly activated O₂⁻ formation which ceased after 8–15 min. In agreement with a recent report (Korchak et al., 1984), NADPH oxidase activation by fMet-Leu-Phe was rapidly terminated upon addition of a 10-fold excess of its competitive antagonist, N-t-butoxycarbonyl-t-phenylalanyl-t-leucyl-t-phenylalanine, suggesting that the continuous occupation of formyl peptide receptors by agonist is required to maintain O₂⁻ formation. As no competitive antagonists for ATP and UTP were available, we used hexokinase reactions to remove the nucleotides from the reaction mixtures. Hexokinase catalyses the phosphorylation of glucose and, thereby, the dephosphorylation of ATP to ADP. Yeast hexokinase rapidly terminated O₂⁻ generation induced by ATP and gradually inhibited that induced by UTP, corresponding to the findings that ATP is a much better substrate for yeast hexokinase than is UTP (Colowick, 1973), and that both ADP and UDP are not efficient activators of O₂⁻ formation. Thus, the continuous presence of ATP and UTP was essential to maintain O₂⁻ formation. In addition to reversibility, activation of NADPH oxidase by fMet-Leu-Phe and nucleotides depended on the presence of extracellular Ca²⁺ (1 mM). In the absence of free Ca²⁺, these stimuli did not activate O₂⁻ formation. Mg²⁺ (1 mM) was no substitute for Ca²⁺ and did not enhance O₂⁻ formation in the presence of Ca²⁺ (results not shown).

In order to elucidate the role of G proteins in NADPH oxidase activation by extracellular nucleotides, HL-60 cells were treated with pertussis toxin. Pertussis toxin inhibited in a concentration-dependent fashion, activation of NADPH oxidase by fMet-Leu-Phe, ATP and UTP but not by phorbol myristate acetate, which circumvents receptor stimulation by directly activating protein kinase C (Fig. 3). The inhibitory effect of pertussis toxin on the fMet-Leu-Phe- and UTP-induced O₂⁻ generations was half-maximal at 10 ng/ml and was maximal at 100 ng/ml. In contrast to its effects on NADPH oxidase activation by fMet-Leu-Phe and UTP, pertussis toxin inhibited the ATP-induced O₂⁻ generation only by up to 60%. The effect of pertussis toxin on O₂⁻ formation was time-dependent. Half-maximal inhibition of O₂⁻ generation was observed after 30–45 min of treatment. Inhibition of the fMet-Leu-Phe- and UTP-induced O₂⁻ generation was complete after an incubation time of 2 h. In contrast, treatment of the cells with pertussis toxin for up to 3 h did not completely suppress the stimulatory effect of ATP. These results indicate that UTP and ATP did not activate NADPH oxidase by similar mechanisms.

The repeated exposure of human neutrophils to hormonal agonists desensitizes the cells to generating O₂⁻ upon restimulation (Smith et al., 1984). Therefore, desensitization experiments were performed in HL-60 cells. Cells were pretreated with fMet-Leu-Phe, ATP or UTP at maximally stimulatory concentrations, and O₂⁻ generation upon re-exposure to these agents was measured (Table 1). Pretreatment of the cells with fMet-Leu-Phe desensitized O₂⁻ generation upon re-exposure to the chemotactic peptide but not to ATP or UTP. Conversely, pretreatment with ATP or UTP did not desensitize the cells towards fMet-Leu-Phe but did desensitize them towards both ATP and UTP, a phenomenon known as heterologous desensitization (Smith et al., 1984).

These results prompted us to study the interaction of chemotactic peptides and nucleotides on O₂⁻ formation in HL-60 cells differentiated with dibutylryl cyclic AMP or dimethyl sulfoxide and in human neutrophils. The experiments depicted in Fig. 4 were carried out in the absence of cytochalasin B, which enhances fMet-Leu-Phe-induced O₂⁻ generation by inhibiting receptor sequestration and by expressing new receptors (Jesaitis
et al., 1986). In the absence of cytochalasin B, dibutyryl cyclic AMP-differentiated HL-60 cells generated $O_2^-$ at rates amounting to 30–60% of those in the presence of cytochalasin B upon exposure to UTP (100 $\mu$M) and fMet-Leu-Phe (1 $\mu$M) (see Figs. 1, 3 and 4). UTP and ATP at concentrations of up to 10 $\mu$M did not activate NADPH oxidase in the absence of cytochalasin B. UTP (0.1–10 $\mu$M) enhanced in a concentration-dependent manner $O_2^-$ generation induced by fMet-Leu-Phe at submaximally and maximally stimulatory concentrations by up to 8-fold. In addition, UTP made the cells responsive to a non-stimulatory concentration of fMet-Leu-Phe (1 $\mu$M), a process called priming (McPhail & Snyderman, 1984; Rossi, 1986). Similar results were obtained with ATP as with UTP. Upon exposure to fMet-Leu-Phe, dimethyl sulphoxide-differentiated HL-60 cells generated $O_2^-$ at much lower rates than dibutyril cyclic AMP-differentiated cells (Table 2). This finding is in agreement with a previous report showing that dibutyril cyclic AMP-differentiated cells expressed much higher numbers of formyl peptide receptors than dimethyl sulphoxide-differentiated cells (Chaplinski & Niedel, 1982). In dimethyl sulphoxide-differentiated HL-60 cells, nucleotides at concentrations up to 100 $\mu$M did not activate NADPH oxidase. However, ATP and UTP potentiated fMet-Leu-Phe-induced $O_2^-$ generation. By analogy to dimethyl sulphoxide-differentiated HL-60 cells, nucleotides per se failed to activate NADPH oxidase in human neutrophils. In the absence of cytochalasin B, UTP enhanced the effect of fMet-Leu-Phe in neutrophils by 3-fold, whereas in the presence of cytochalasin B, UTP stimulated $O_2^-$ formation only by 42%.

In human neutrophils, the effects of fMet-Leu-Phe are inhibited by activators of adenylate cyclase, such as 5'-N-ethylcarboxamidoadenosine, isoproterenol, prostaglandin E1, and cholera toxin (Bokoch & Gilman, 1984; Lad et al., 1985b; Cronstein et al., 1985; Gryglewski et al., 1987). Furthermore, these agents differentially inhibit $O_2^-$ formation induced by different classes of

HL-60 cells were harvested, suspended at a density of $2 \times 10^6$ cells/ml in buffer for determination of $O_2^-$ generation and incubated for 10 min in the presence of buffer (control), fMet-Leu-Phe, ATP or UTP at the indicated concentrations at 37°C. Thereafter, stimuli were diluted by suspending the cells in a 10-fold excess of volume of buffer not supplemented with CaCl$_2$ and stimulus. Cells were harvested and assayed for $O_2^-$ generation with various stimuli. The means of three experiments performed with different preparations of HL-60 cells are given; these varied by less than 10%.

HL-60 cells were cultured for 48 h in the presence of 0.2 mM-dibutyryl cyclic AMP to induce expression of formyl peptide and nucleotide receptors. Thereafter, cells were harvested and suspended in the buffer for O$_2^\cdot$ generation containing no dibutyryl cyclic AMP. The activators of adenylate cyclase, 5'-N-ethylcarboxamidoadenosine (NECA), isoproterenol, prostaglandin E$_1$, or buffer (control) were added to reaction mixtures at the indicated concentrations 3 min prior to fMet-Leu-Phe, ATP or UTP. Cells were treated with cholera toxin or its carrier (control) for 2 h according to the procedure described in the legend to Fig. 3. Data shown represent the means of four to seven experiments carried out with different preparations of HL-60 cells which varied less than 10%.

hormone agonist. In preliminary experiments, the concentrations of adenylate cyclase activators given in Table 3 were found to be maximally inhibitory on O$_2^\cdot$ formation (results not shown). In dibutyryl cyclic AMP-differentiated HL-60 cells, 5'-N-ethylcarboxamidoadenosine inhibited the effects of maximally stimulatory concentrations of fMet-Leu-Phe and UTP by 33 and 47% respectively, whereas the effect of ATP was inhibited by only 15%. Isoproterenol and prostaglandin E$_1$ inhibited fMet-Leu-Phe- and ATP-induced O$_2^\cdot$ formation by < 10% and UTP-induced O$_2^\cdot$ formation by up to 45%. Pretreatment of the cells with cholera toxin reduced the effects of fMet-Leu-Phe and UTP by up to 70%, whereas the effect of ATP on NADPH oxidase was almost unaffected.

**DISCUSSION**

As pertussis toxin inhibits the effects of ATP and UTP on NADPH oxidase, and as activation of O$_2^\cdot$ formation exhibits a high degree of specificity for relatively few purine and pyrimidine nucleotides, it is likely that the effects of nucleotides are receptor-mediated. In addition, ATP and UTP activate O$_2^\cdot$ formation at concentrations required to activate other cellular functions presumably occurring in vivo (Gordon, 1986). Furthermore, NADPH oxidase activations by ATP, UTP and fMet-Leu-Phe have several characteristics in common, i.e. dependence on extracellular Ca$^{2+}$, reversibility, requirement for continuous presence of agonist, desensitization, recruitment by cytochalasin B and inhibition by activators of adenylate cyclase.

In agreement with previous reports, we found that ATP and adenosine 5'-O-(3-thiotriphosphate) are potent purinergic agonists in HL-60 cells (Dubay et al., 1987; Cowen et al., 1988). Interaction of purinoceptors with...
pertussis toxin-sensitive G proteins has been documented only for inhibition of adenylate cyclase in rat hepatocytes but not for activation of a purinergic effector system, i.e. phospholipase C (Okajima et al., 1987). Thus, the pertussis toxin sensitivity of NADPH oxidase activation by purinergic agonists is a novel feature of purinoceptors. In addition, the purinoceptors in HL-60 cells show some further properties which are different from those of other purinoceptors. In platelets, ADP is the most potent agonist, and in mast cells only ATP acts as an agonist at purinoceptors (Gordon, 1986). Furthermore, α,β-methylene-ATP and β,γ-methylene-ATP are P₆₅-purinoceptor agonists but are not activators of NADPH oxidase (Burnstock & Kennedy, 1985). Finally, adenylyl imidodiphosphate is an agonist at P₆₅-purinoceptors but not at purinoceptors of HL-60 cells (Rice & Singleton, 1987). These data suggest that the purinoceptors in HL-60 cells do not belong to hitherto characterized purinoceptor subtypes.

In human neutrophils, pertussis toxin and activators of adenylate cyclase differentially inhibit O₂⁻ formation induced by various classes of hormonal agonists (Lad et al., 1985a; Gryglewski et al., 1987; Verghese et al., 1987; Shirato et al., 1988). NADPH oxidase activation by UTP in HL-60 cells is more sensitive towards inhibition by pertussis toxin and activators of adenylate cyclase than that induced by ATP. These data clearly indicate that UTP does not mediate its effects via purinoceptors. The results strongly support recent data suggesting the existence of pyrimidinoceptors (Kügelen et al., 1987; Häussinger et al., 1987), which, at least in the case of HL-60 cells, interact with pertussis toxin-sensitive G proteins. UTP appears to be the endogenous ligand for this pyrimidinoceptor, as other pyrimidine nucleotides are far less effective activators of O₂⁻ formation. Activation of NADPH oxidase by pyrimidine nucleotides shows a nucleotide specificity different from that for the activation of other cellular systems, suggesting heterogeneity among pyrimidinoceptors (Shirasawa et al., 1983; Hardebo et al., 1987; Kügelen et al., 1987; Häussinger et al., 1987). UTP and ATP both potentiate O₂⁻ formation induced by chemotactic peptides even with both classes of stimuli present at maximally stimulatory concentrations, indicating that these agents activate NADPH oxidase via different receptors. Agonists acting via distinct receptors may additively activate G proteins, and thus may greatly amplify activation of effector systems, i.e. NADPH oxidase and/or phospholipase C. In addition, occupation of purino- and pyrimidinoceptors with agonists may increase the number and/or affinity state of formyl peptide receptors or may prevent their sequestration. The latter possibilities are supported by the finding that cytochalasin B diminishes the potentiating effect of UTP, indicating that both agents act, at least in part, by a mechanism they have in common (Jesaitis et al., 1986).

In contrast to dibutyryl cyclic AMP-differentiated cells, ATP and UTP do not activate NADPH oxidase in dimethyl sulphoxide-differentiated HL-60 cells and in human neutrophils, but they do potentiate O₂⁻ formation induced by fMet-Leu-Phe. Nucleotides are released into the extracellular space under various physiological and pathological conditions (Goetz et al., 1971; Shirasawa et al., 1983; Gordon, 1986; Forsberg et al., 1987; Hardebo et al., 1987). Thus, ATP and UTP may play roles as intercellular signal molecules in the regulation of O₂⁻ formation. The physiological function of nucleotides apparently is to potentiate NADPH oxidase activation rather than to activate the enzyme per se. As ATP and UTP per se lead to activation of NADPH oxidase in dibutyryl cyclic AMP-differentiated HL-60 cells, possibly due to the expression of very high numbers of purino- and pyrimidinoceptors, these cells provide a useful model system to study purinergic and pyrimidinergic activation of NADPH oxidase.

The authors are grateful to Dr. Walter Rosenthal for helpful discussion, to Mrs. Evelyn Glass for valuable technical assistance, to the laboratory staff of the Institute for donating blood and to Mrs. Rosemarie Krüger for help in the preparation of the manuscript. This work was supported by grants of the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie.
