Dr. rer. nat.

**der Fakultät für Chemie und Pharmazie**

**der Universität Regensburg**

vorgelegt von

**Ludwig K. A. Pisl**

aus Regensburg

**Regensburg 2014**

Die Arbeit wurde angeleitet von:

Prof. Dr. O. Reiser

Promotionsgesuch eingereicht am:

18. Februar 2014

Promotionskolloquium am:

11. April 2014

Prüfungsausschuss:

Vorsitz: Prof. Dr. S. Elz

1. Gutachter: Prof. Dr. O. Reiser

2. Gutachter: Prof. Dr. K. Zeitler

3. Gutachter: Prof. Dr. J. Wegener

Der experimentelle Teil der vorliegenden Arbeit wurde in der Zeit von Oktober 2010 bis Januar 2014 unter der Leitung von Prof. Dr. O. Reiser am Lehrstuhl für Organische Chemie der Universität Regensburg und von September 2011 bis Oktober 2011 an der Universitat Autònoma de Barcelona (Spanien) bei Prof. Dr. R. M. Ortuño angefertigt.

Besonders bedanken möchte ich mich bei Herrn Prof. Dr. O. Reiser für die Aufnahme in seinen Arbeitskreis, die Überlassung des interessanten Themas, die anregenden Diskussionen, die stete Unterstützung, sowie die Ermöglichung des Auslandsaufenthaltes in Barcelona.

*für Bernadette*

## A Introduction – Synthesis and applications of cyclopropanated furan and pyrrole derivatives

### 1 Introduction

Cyclopropanated furan and pyrrole derivatives represent a class of highly valuable compounds with unique structural features that have been utilized in a number of elegant synthetic approaches so far. Their versatile reactivity makes them powerful intermediates and allows for various orthogonal functionalizations and transformations. This account will focus on compounds with the general substructures of **1** and **2** (figure 1).

**Figure 1.** General structure of cyclopropanated furan (X = O) and pyrrole (X = NR) derivatives and possible transformations of them.

Figure 1 illustrates the core structure of the title compounds and the general scope for their further transformation. A brief history of the first literature precedents will be given, followed by recent methods for the preparation of compounds like **1** and **2**, with a special focus on enantioselective reactions. In addition, applications in the synthesis of natural products and other synthetically useful compounds will be presented. Cyclopropanated benzofurans and indoles as well as doubly cyclopropanated furans have also been described, but will not be covered in here.

## 2 Methods for the preparation of cyclopropanated furan and pyrrole derivatives

The first examples of cyclopropanated furans date back to the 1960s, when *Müller* and co-workers used diazomethane and copper(I)-bromide for the cyclopropanation of furan to synthesize homofuran **1** ( $X = O$ ,  $R^1 = R^2 = R^3 = H$ ).[1] While cyclopropanation of furan by photo-induced decomposition of diazo compounds was already reported in 1958 by *Schenck and Steinmetz*,[2, 3] the decomposition of diazoesters catalyzed by dirhodium tetraacetate for cyclopropanation reactions of furan itself and derivatives thereof was carried out by *Wenkert et al.* in the 1990s.[4-6] Furthermore, they recognized the intrinsic instability of the unsubstituted furanocyclopropane moiety bearing an ester group at the three-membered ring, which was put to an advantage with the synthesis of highly unsaturated open-chain aldehydes via ring opening / isomerization. More importantly, the authors could already prove that electron-withdrawing groups on the furan ring increase the stability of the cyclopropanated adducts dramatically, thus allowing a multifaceted follow-up chemistry. On the other hand, first efforts for the cyclopropanation of pyrrole derivatives and their application in cycloaddition reactions were conducted by *Fowler* in the early 1970s.[7-9] Copper complexes with homoscorpionate based ligands were shown to be able to catalyze cyclopropanation reactions of furans, although only in racemic form.[10, 11] Current methods for the enantioselective synthesis of cyclopropanated furans (**1**) and pyrrols (**2**) are based on the decomposition of diazo compounds with chiral metal complexes.[12] Copper(I)-complexes with chiral bis(oxazoline) (box, **5-7**) or aza-bis(oxazoline) (azabox, **8-9**) ligands have been shown to be superior catalysts for intermolecular cyclopropanation reactions of furans (scheme 1).[13-15] However, only very few derivatives are accessible in enantiomerically pure form so far (scheme 1, lower part).

**Scheme 1.** Top: Enantioselective cyclopropanation of 2-methyl furoate **3** reported by Reiser *et al.* Depending on the absolute configuration of the applied ligand, both enantiomers of cyclopropane **4** can be obtained in enantiomerically pure form and multi-gram quantity.[15] Bottom: Overview of the most successful results in literature for enantioselectively cyclopropanated furan and pyrrole derivatives with the applied ligand (or catalyst) and the corresponding reference (*red* values in brackets were obtained after recrystallization).

Chiral rhodium(II)-catalysts like **10** have also emerged for such kind of transformations, however, with limited success (**16**, **17**).[16] For the preparation of cyclopropanated pyrroles **2** (see **17** and **18**) no direct asymmetric cyclopropanation reaction is known so far. Nevertheless, other methods for accessing enantiomerically pure **18** have been achieved (see main part chapter **B 1.3.1**).[17, 18] New accomplishments and optimizations of asymmetric cyclopropanation reactions of furan and pyrrole derivatives will be presented in the main part of the present thesis. In the following chapter, possible transformations of the compounds presented above will be discussed.

### 3 Transformations of cyclopropanated furans and pyrroles

The simplest representatives of the title compounds are homofuran **1** ( $\text{X} = \text{O}$ ) and homopyrrole **2** ( $\text{X} = \text{NR}$ ). These molecules have been employed in a manifold of cycloaddition reactions, as they exhibit unique properties as masked 1,5-dipoles.[19-22]

Under thermal activation, **1** or **2** can rearrange to form compounds of type **19**, being a highly reactive intermediate that can undergo [5+2] cycloaddition reactions with suitable dienophiles to form seven-membered ring systems **20** with ease (scheme 2). By density functional theory (DFT) calculations it was shown that homofuran **1** and homopyrrole **2** display relatively low distortion energies for the reaction to **19**, which was claimed to be the main reason for their ability to undergo metal-free [5+2] cycloaddition reactions.[23]

**Scheme 2.** Reactivity of homofuran **1** (X = O) and homopyrrole **2** (X = NR). Under thermal conditions **1** or **2** can serve as masked 1,5-dipoles for [5+2] cycloaddition reactions, yielding products like **21-23**. [7, 8, 23, 24]

*Tanny and Fowler* could show that also cyclopropanated pyrrole derivatives bearing an ethyl ester moiety at the 6-position are able to undergo analogous reactions with suitable nucleophiles.[25] On the other hand, racemic cyclopropanated furan **24** was shown to undergo a [4+2] cycloaddition reaction with diethyl azodicarboxylate (DEAD).[26] Nevertheless, applications of homofuran and homopyrrole derivatives are limited, and cyclopropanated furan and pyrrole esters (**4**, **15**, **18**, **24**) proved to be superior building blocks for synthesis, since access to enantiomerically pure material is feasible and possible transformations are more diverse. Figure 2 gives an overview of accessible target compounds (**25-34**) and details on their syntheses and properties will be discussed in the following sections.

**Figure 2.** Overview of accessible compounds from cyclopropanated furan and pyrrole esters (mGlu = metabotropic glutamate; ACC = aminocyclopropanecarboxylic acid).

### 3.1 Transformations of cyclopropanated furan derivatives

A rhodium catalyzed cyclopropanation of furan **35** with diazo compound **36** was used for the total synthesis of racemic 12-hydroxyeicosatetraenoic acid **38** by *Fitzsimmons* and co-workers via an intermediary cyclopropane and open-chain aldehyde **37** (scheme 3).[27] Hereby, the authors made use of the cyclopropane ring unraveling process introduced earlier by *Wenkert et al.*[28]

**Scheme 3.** Synthesis of 12-hydroxyeicosatetraenoic acid **38** by *Fitzsimmons et al.* through cyclopropanation of furan **35** with diazoester **36** and subsequent cyclopropane unraveling.[27]

In 1999, *Monn* and colleagues synthesized bicyclic amino acid LY379268 (**32**) in ten steps from furan ester **24** and found it to be a remarkably potent agonist for group II metabotropic

glutamate (mGlu) receptors.[29, 30] A powerful methodology for the construction of *trans*-4,5-disubstituted  $\gamma$ -butyrolactones **43** from cyclopropanated furan **4** was presented by *Reiser* and co-workers,[13, 15, 31, 32] which enables the access to a manifold of natural products, including Paraconic acids, Eudesmanolides, Elemanolides, Guaianolides and Xanthanolides (scheme 4).[33-37] After ozonolytic cleavage of the double bond in **4** with reductive work-up, a diastereoselective addition of various nucleophiles (Nu) to the aldehyde function of **39** can be performed, which yields either the *Felkin-Ahn* or *Cram-Chelate* products (depending on the nucleophile) in high selectivity.[36] Base-induced saponification of the oxalic ester moiety in **40** leads to donor-acceptor (DA) substituted cyclopropane **41**, which undergoes a retroaldol/lactonization sequence (via **42**) to yield diversely substituted lactones of type **43**.

**Scheme 4.** Synthetic sequence for the stereoselective preparation of *trans*-4,5-disubstituted  $\gamma$ -butyrolactones **43** as precursors for the synthesis of sesquiterpenelactone based natural products (FA = *Felkin-Ahn*).[38]

This method has been applied successfully for the construction of several natural products, amongst them various Paraconic acids (e.g. Roccellaric acid **25**),[31, 39] Arglabin<sup>TM</sup> **26**[40] and Arteludovicinolide A **30** (see also figure 2).[41] Another promising method for the application of cyclopropanated furans is the acid-catalyzed cyclopropane ring opening reaction followed by lactonization that is depicted in scheme 5. It has to be noted that related transformations were reported earlier.[42, 43] As an application of this methodology *cis*-fused 5-oxofuro[2,3-*b*]furans of type **44** and **45** can be generated, with an carboxylic acid function either in 2- or 3-position (**44** and **45**) depending on the furan starting material being used.

**Scheme 5.** Facile access to *cis*-fused 5-oxofuro[2,3-*b*]furans of type **44** and **45** based on acid-catalyzed cyclopropane opening and subsequent lactonization starting from 2- or 3-substituted furans.[44, 45]

While bicyclic lactone **45** can serve as starting point into several spongiane diterpenoid natural products (e.g. Norrisolide, Macfarlandin C, Cheloviolene A and B),[46] **44** has been successfully used for the enantioselective synthesis of (-)-Paeonilide **27** in ten steps from cyclopropane **15** (in 83% *ee*, see main part chapter **B 1.2** for details). Recently, tetrahydrofuran derivative **31** and various related compounds were prepared from cyclopropane **4** as potent histamine hH<sub>3</sub> receptor antagonists (figure 2).[47]

### 3.2 Transformations of cyclopropanated pyrrole derivatives

In contrast to the furan derivatives presented above, cyclopropanated pyrroles have been applied for the construction of a variety of biologically relevant nitrogen containing compounds (figure 2). For instance, so-called  $\beta$ -aminocyclopropanecarboxylic acids ( $\beta$ -ACCs **33**)[17, 48-52] – conformationally constrained  $\beta$ -amino acids – have been successfully employed in a variety of artificial peptide sequences as rigidifying compounds. The combination of **33** with  $\alpha$ -amino acids allowed in peptides the construction of new secondary structural motifs,[53] biologically active ligands toward Neuropeptide Y, Orexin and CPRG receptors [54-57] as well as organocatalysts (see main part chapter **B 4** for details).[58, 59] Comparable to the procedure in scheme 4, an ozonolytic cleavage of the remaining double bond in **18** was again the key step for the preparation of these valuable unnatural amino acids. Besides opening the pyrrol ring that led to the synthesis of conformationally constrained amino acids **33**, pyrrole derivative **18** could also be employed in transformations that selectively open the cyclopropane ring. For example, **18** can be converted into 4-functionalized pyrrolidin-2-one **28** within four steps. From there, multiple functionalizations

of **28**, as well as the synthesis of (*S*)-Vigabatrin **29** have been accomplished.[18] Cyclopropane **18** was also subjected to a *Povarov* reaction for the construction of complex heterocyclic compounds like **34** and **51** (scheme 6).[60] In this case aromatic imines, which are in situ formed from aldehydes **46** or **48** and aniline derivatives **47** or **49**, undergo a [4+2] cycloaddition reaction with cyclopropanated pyrrole **18** in order to establish a six-membered ring system.

**Scheme 6.** Lewis acid catalyzed multicomponent reactions for the construction of complex heterocyclic compounds **34** and **51** (mw = microwaves, single fragments are color coded for clarity).[60]

Depending on the reaction conditions, these intermediates can react further in different pathways to form either *cis*-4,5-disubstituted pyrrolidinones **34** or compounds like **51**, where pyrrole **50** was added as an external nucleophile for trapping the intermediary iminium ion resulting from cyclopropane opening. *Landais and Renaud et al.* were able to add phenylthiol to a cyclopropanated pyrrole (X = NCO<sub>2</sub>Me, R<sup>1</sup> = R<sup>2</sup> = H, R<sup>3</sup> = Et) under UV irradiation via a free-radical mechanism, however, only in 32% yield and a 1:1 mixture of diastereomers for this single example.[61] All in all, the literature examples presented above demonstrate the synthetic utility of cyclopropanated furans and pyrroles. Moreover, it seems obvious that from such a class of important molecules new and creative ideas for their transformations will arise in the future. In the present thesis, attempts for the optimization of heterocycle cyclopropanation, as well as subsequent transformations of the latter were carried out. The results are presented in the following.

## B Main part

### 1 Asymmetric cyclopropanations of furan and pyrrole derivatives

#### 1.1 Synthesis of the ligands for asymmetric cyclopropanation reactions

A central part of the present thesis deals with the asymmetric cyclopropanation of heterocyclic substrates using chiral copper(I)-complexes. Thus, we have focused on the application of the well-established aza-bis(oxazoline) (azabox) ligands **56** that were developed in the *Reiser* group[62, 63] and have already found various successful applications in asymmetric catalysis.[64-66] Structurally related to the parent semicorrines **52**,[67-69] the aza-semicorrines **53**,[70] and the bis(oxazolines) (box, **54**),[71-75] azabox ligands combine several positive aspects like accessibility from the chiral pool (starting from amino alcohols), a high degree of diversity, and the potential of functionalization and/or immobilization on the central nitrogen atom (figure 3).[76-80] One step further from box and azabox ligands was made by *Tang et al.* and *Gade et al.* with the invention of tripodal tris(oxazoline) (tox) ligands with an additional binding site (figure 3).[81, 82] However, the basis of box, azabox and tox ligands was made by *Brunner et al.*, who introduced oxazolines to catalysis already in 1989.[83, 84]

**Figure 3.** General chemical structures of different N-containing bi- and tridentate ligands for catalysis.

The original synthesis of azabox ligands published in 2000 was based on the direct coupling of two molecules of aminoxazoline **57** promoted by benzaldehyde **48** (*method A*, table 1).[62] Using this method it was possible to prepare ligands with *tert*-butyl and *iso*-propyl substituents, however, yields were not always satisfying and there was no access to asymmetrically substituted ligands with a higher degree of diversity. In 2003, *Reiser* and

co-workers presented a new solution to such problems (*method B*, table 1). Thus, by making use of alkylated oxazolidinones **59** as coupling partners with the established aminooxazolines **57** new types of ligands were accessible, partially in better yields.[63] Table 1 gives an overview of all so far synthesized azabox ligands (with free NH), the method of preparation, as well as the corresponding yields of the final coupling step, while figure 4 shows the chemical structures of the corresponding ligands.

**Table 1.** Overview of all so far synthesized azabox ligands (with free NH) from the *Reiser* group.

**Figure 4.** Overview of all so far synthesized azabox ligands (with free NH) from the *Reiser* group.

Scheme 7 gives an overview of the exemplary synthesis of *tert*-butyl-azabox **8** following the improved methodology.[63]

**Scheme 7.** Exemplary reaction scheme for the synthesis of *tert*-butyl substituted azabox ligand **8** following the improved methodology of *Reiser et al.*, and functionalization of the central N-atom to yield **9** and **74**.

Reduction of the amino acid **69** according to a protocol of *McKennon* and *Meyers*[88] yields amino alcohols **70** in good to excellent yields,[89] which serve as starting point for both coupling partners. On the one hand, **70** is cyclized to the corresponding amino oxazoline **71** by the use of in situ prepared cyanogen bromide (protocol of *Poos et al.*).[90-92] On the other hand, amino alcohol **70** is transformed into ethoxyoxazoline **73** in a two-step procedure. First, **70** is cyclized to the oxazolidinone **72** by the use of diethylcarbonate under basic conditions and then alkylated using *Meerwein's* reagent[93-95] to yield **73**. The final acid catalyzed step couples the amino oxazoline **71** with the ethoxyoxazoline **73** to yield azabox ligands in varying yields, strongly depending on the nature of the substituents (see table **1** for details).

Further functionalization of the central nitrogen atom can be readily achieved by deprotonation with *n*-butyl lithium, followed by trapping with a suitable electrophile (scheme 7). As the new synthesis of azabox ligands by *Reiser et al.* (scheme 7; ref. [63]) was based on studies by *Gawley et al.*, who investigated the reactivity of ethoxyoxazolines **75** toward amine nucleophiles (scheme 8),[96] the idea for developing a simpler approach without the need for an aminooxazoline came to our mind.

**Scheme 8.** Reaction of ethoxyoxazoline **75** with secondary amine **76** investigated by *Gawley et al.*[96]

As was already shown by *Gawley* and co-workers, ethoxyoxazolines are capable of reacting with secondary amines, thus, making use of the high reactivity of **78**, they could be applied for a much more convenient synthesis of azabox ligands. Based on these results **78**, should also react with ammonia or primary amines in order to form aminooxazolines of type **79**. These could further react with a second molecule of ethoxyoxazoline **78** to form azabox ligands with free NH or substituted derivatives (**80**), respectively (scheme 9).

**Scheme 9.** Proposed strategy for a more convenient synthesis of azabox ligands **80** based on the condensation of ammonia or primary amines with two equivalents of alkylated oxazolidinones **78**.

For the investigation of our proposed strategy we have applied two different nitrogen sources, namely a solution of ammonia in methanol (7 M) and *N*-benzylamine. Main criteria for the choice of amines were manageability (e.g. boiling point) and the potential resulting target molecules. Furthermore, all experiments were carried out with *iso*-propyl substituted ethoxyoxazoline **75**, as its starting material *L*-valine is among the most abundant and inexpensive alternatives herein (compared for instance to *tert*-leucine **69**). Table 2 summarizes the experiments carried out to study the proposed strategy.

**Table 2.** Attempts for the preparation of azabox ligands by direct coupling with amines.<sup>1</sup>

entry <sup>a)</sup>	N-source	product	solvent	catalyst	temperature [°C]	yield [%] <sup>d)</sup>

a) 1.89 mmol (2 equiv) **75**, 0.95 mmol (1 equiv) R-NH<sub>2</sub>, 0.09 mmol (0.1 equiv) *p*-TSA, 5 ml solvent, 24 h; b) ratio **75**/R-NH<sub>2</sub> (2:3); c) 0.95 mmol **82** (1 equiv), 4.75 mmol **75** (5 equiv), 0.10 mmol (0.1 equiv) *p*-TSA, 5 ml toluene, 24 h, reflux; d) isolated yields after column chromatography; e) no azabox formed, yield of mono-substitution product **82**.

Looking at table 2 it can be seen that the reaction did indeed work, but only in rather poor yields. Reactions employing a solution of ammonia in methanol (entries 1-3) resulted in unsubstituted azabox **60** with yields between 8% and 16%. Using *N*-benzylamine as the nucleophile, only the mono-substitution product **82** was obtained instead of the desired azabox **81** (entries 4-5). Moreover, an attempt of transforming secondary amine **82** into the desired *N*-benzyl-azabox **81** with an excess of ethoxyoxazoline **75** failed, probably due to the high steric demand of **82** (entry 6). In regard of the overall low yields for this approach no further investigations were conducted.

Besides the well-known reactivity of ethoxyoxazolines toward nucleophiles, it is also known that 2-chloro- and 2-bromooxazolines are capable of undergoing substitution reactions with a variety of nucleophiles. This was first shown by *Sam* and *Plampin* in 1964 when they investigated the synthesis of new benzoxazole derivatives as skeletal muscle relaxants (scheme 10).[97]

<sup>1</sup> Results are partially taken from the Bachelors thesis of M. Halder (supervised by L. Pilsl).

**Scheme 10.** Synthesis of aza-bis-benzoxazole **84** from 2-chlorobenzoxazole **83** by *Sam* and *Plampin*.

Although, the resulting double coupling product **84** was rather an unwanted by-product in their case, it nevertheless demonstrated the possibilities of such substrates. More recently, *Bellemin-Laponnaz* and *Gade et al.* were reacting 2-bromooxazolines **85** with imidazoles for the synthesis of N-heterocyclic carbene (NHC) ligands (scheme 11).[98]

**Scheme 11.** Synthesis of NHC ligands from 2-bromooxazoline **85** by *Bellemin-Laponnaz* and *Gade et al.*[82]

In terms of such a reactivity pattern, it seemed applicable to try substitution of 2-bromooxazolines with ammonia in order to obtain azabox ligands (scheme 12). Direct lithiation of the 2-*H*-oxazoline **87**<sup>2</sup> by the use of *tert*-butyllithium, followed by in situ bromination of the lithiated species with 1,2-dibromo-1,1,2,2-tetrafluoroethane is an established methodology for the preparation of bromooxazolines.[99-101]

**Scheme 12.** Attempt for the direct lithiation-bromination-amination strategy for the synthesis of azabox **8** based on 2-*H*-oxazoline **87**.

Due to the fact that bromooxazolines are not permanently stable and tend to isomerize,[100] it was chosen to generate them in situ and directly convert them into the corresponding aminooxazolines/azabox ligands. Subsequent substitution of the bromide with methanolic ammonia was intended to yield an intermediary aminooxazoline of type **79**, which could then further react to the desired azabox ligand **8** (scheme 12). However, this strategy did not lead to any product formation, and upon the failure of this approach no further efforts were made

<sup>2</sup> Oxazoline **87** was provided by M. Knorn.

to study such coupling reactions in more detail. In the course of this project the established synthesis procedure of *Reiser et al.*[63] was applied for the preparation of the required ligands.

## 1.2 Asymmetric cyclopropanation of furan derivatives

While cyclopropanation products of furan with diazoacetates have been shown to be rather unstable and tend to rearrange (see also introduction),[10, 12, 13, 102, 103] the enantioselective cyclopropanation of furan-2-carboxylic acid methyl ester **3** is a well-established process. It was developed in the *Reiser* group and is regularly performed on a multi-gram scale in our laboratories.[13-15, 31] Since then, this methodology was applied for a variety of  $\gamma$ -butyrolactone-containing natural product syntheses[32, 34-36, 39-41] and other synthetically useful compounds.[47, 60] In contrast, furan-3-carboxylic acid **88** was used as starting point for the synthesis of (-)-Paeonilide by *Harrar* and *Reiser*.<sup>[45]</sup> The key intermediate for their synthesis was cyclopropanated furoic ester **15** from which on they were able to synthesize **27** in ten steps and an overall yield of 14% (12 steps, 4.4% yield, 7.7% brsm, starting from commercially available furan-3-carboxylic acid **88**). However, due to the lack of complete stereocontrol during the crucial cyclopropanation step, (-)-Paeonilide **27** could only be prepared in a maximum of 83% enantiomeric excess. Scheme 13 depicts an overview of the synthesis of (-)-paeonilide **27** by *Harrar* and *Reiser*.

**Scheme 13.** Enantioselective synthesis of (-)-Paeonilide **27** from 3-furoic acid **88** (via **15**, **44**, **89**, **90**) by *Harrar* and *Reiser*.<sup>[45]</sup>

Table 3 summarizes all so far reported attempts for the enantioselective cyclopropanation of **91** (entries 1-8). When applying ethyldiazoacetate (R = Et) a maximum of 31% yield and 83% *ee* could be reached (entry 1), while for *tert*-butyl substituted analogue **15** 38% yield and analogous 83% *ee* could be realized in the best case so far (entry 6). As these results display the state-of-the-art for this important molecule, we envisioned to find a reasonable solution to this problem.

**Table 3.** Asymmetric cyclopropanation of furan-3-carboxylic acid methyl ester **91**. [14, 39, 45]

a) 3.97 mmol (500 mg) **91**, 1 mol% Cu(OTf)<sub>2</sub>, 2.2 mol% ligand, 1 mol% PhNHNH<sub>2</sub>, 1.5 equiv diazoester, 3 ml DCM; b) ref. [45]; c) ref. [39]; d) ref. [14]; e) 102.4 mmol (12.91 g) **91**; f) isolated yield; g) determined by chiral HPLC; h) 19%, > 99% *ee* after single recrystallization from *n*-pentane.

From earlier studies with box and azabox ligands it is known that the derived copper complexes predominantly form 1:2 complexes with two ligand molecules bound to the metal center,[66, 104] thus the ratio for our experiments was set to 0.5 (1 mol% Cu/2.2 mol%

ligand; entries 9-13) in contrast to the former investigations (0.8; entries 1-8). When the two applied ligands **8** and **9** are directly compared to each other one clearly recognizes that the size of the substituent on the central nitrogen atom is rather negligible with regard to selectivity (92-94% *ee*, entries 9-12). However, in terms of yield the ligand with the free NH **8** shows significantly better results compared to its methylated analogue **9** (entries 9/10 and 11/12). Furthermore, the substantial influence of temperature on the performance of the reactions becomes obvious when comparing the yields of entries 9 with 11, and 10 with 12, respectively. A significant drop of the yields for both catalysts becomes evident when the temperature is lowered from 0 °C to -10 °C, independent of the applied ligand (55% to 31% for **8**, and 38% to 21% for **9**). Best results were obtained when using *t*Bu-azabox **8** with free NH at 0 °C, yielding **15** in thus far surpassing 55% and excellent 92% *ee*. This observation intrigued us to perform a large scale experiment under the very same conditions applied in entry 9. Fortunately, when upscaling the reaction only a low decrease in yield and enantioselectivity was observed, giving rise to cyclopropane **15** in 47% isolated yield and 89% *ee*. Most importantly, the product could be recrystallized from *n*-pentane to yield **15** in enantiopure form (table 3, entry 13, and figure 4). Figure 4 depicts the analytical chiral HPLC chromatogram of enantiopure (*S,R,S*)-(-)-**15**.

**Figure 4.** Analytical HPLC chromatogram for enantiomerically pure (*S,R,S*)-(-)-**15**. Phenomenex Lux Cellulose-2, *n*-heptane/*i*PrOH = 99:1, flow = 1.0 ml/min,  $\lambda_{\max}$  = 254 nm ( $t_r$  = 12.3 min (+),  $t_r$  = 16.7 min (-); for racemic data see ref. [45]).

All in all, three significant parameters for the cyclopropanation reaction of 3-furoic acid were modified compared to the original efforts by *Harrar*[45] in order to yield optimum results.

The type of ligand was exchanged from box to azabox ligands, the ratio of metal to ligand (stoichiometry of catalyst) was changed from approximately 1:1 to 1:2, and finally – and also most importantly – suitable conditions for a recrystallization of crude **15** were found, giving access to enantiopure material in gram scale for the first time. Based on the herein presented results, the synthesis of enantiopure (-)-Paeonilide, as well as its natural enantiomer (+)-Paeonilide, is currently ongoing in the *Reiser* group.

## 1.3 Asymmetric cyclopropanation of *N*-Boc-pyrrole

### 1.3.1 Synthesis of (*S,S,S*)-(-)-103

In table 4 the state-of-art results for the asymmetric cyclopropanation of *N*-Boc-pyrrole **101** are summarized. Eleven different ligands have been employed so far, among them azabox (**8**, **9**, **60**, **95**), regular box (**7**, **96**, **97**), as well as box ligands with secondary binding sites (**93**, **98**, **99**), and a chiral ferrocene based ligand **100** (figure 5).

**Figure 5.** Chemical structures of the employed ligands for asymmetric cyclopropanation approaches of *N*-Boc-pyrrole **101** reported so far.

In all cases besides one (entry 9), methyl diazoacetate was used as the carbene source for those experiments (entries 1-8). When having a look at table 4 it becomes apparent that a level of enantioselectivity better than moderate has not been reached so far. Despite the relatively good yields (max. 63%), the best results in terms of selectivity were obtained when using azabox ligands **8** or **9** (giving 52 and 55% *ee* respectively). This is far from acceptable if one considers using **18** as starting material for amino acid or natural product synthesis.

**Table 4.** Literature results for the asymmetric cyclopropanation of *N*-Boc-pyrrole **101** (for the applied ligands see figure 5).

Interestingly, none of the investigators tried decreasing the temperature in order to improve selectivity, and only in one case an ester group other than methyl (ethyl, entry 9) was applied. Based on the results from table 4, it seems obvious that with the levels of enantioselectivity reached so far, the idea for the development of unnatural amino acids or natural products using said method was rendered meaningless. Nevertheless, it has to be noted that access to enantiomerically pure **18** (in either form) has been accomplished by other methods than asymmetric cyclopropanation. In a cooperation between the *Reiser* group and *Merck Darmstadt*, racemic ( $\pm$ )-**18** could be separated by simulated moving bed chromatography (SMBC) to give about 75 g of either enantiomer and excellent enantiomeric excess (scheme 14).[18, 107] This material was then used for a great variety of applications, especially the

<sup>3</sup> Several reports claimed that (*R,R,R*)-(+)-**18** was formed with the presented ligands (derived from *L*-amino acids), which would be contrary to the results from furan derivatives. In chapter B 1.3.4, it is clearly demonstrated that these claims are wrong, and (*S,S,S*)-(-)-**18** is the major product formed in these reactions.

synthesis of  $\beta$ -amino acids ( $\beta$ -ACCs) for the incorporation into artificial peptides, so-called foldamers (see introduction).

**Scheme 14.** Resolution of racemic **18** via simulated moving bed chromatography (SMBC).[18]

In addition, enantiomerically pure **18** could also be prepared by kinetic enzymatic resolution of racemic ( $\pm$ )-**18** using lipase L-2.[51] However, due to significant limitations in scale this approach was not followed up intensively. On the other hand stock amounts of enantiomerically pure **18** in the *Reiser* group have almost vanished by now, but nonetheless **18** is still of high importance.[60] These facts made us thinking about whether the initial idea of an asymmetric cyclopropanation reaction of *N*-Boc-pyrrole was still the most reasonable strategy. As already mentioned in chapter **B 1.2**, our group has strong expertise in asymmetric cyclopropanation chemistry, facilitating the search for optimal conditions. In the following section the efforts toward enantiomerically pure cyclopropanated pyrrole are presented. Table **5** summarizes all experiments carried out in this investigation. In our studies two major differences were made when compared to the original reports; first *tert*-butyldiazoacetate was used instead of methyl- or ethyldiazoacetate because it is known that the higher degree of steric bulk of the ester group can play a beneficial role for selectivity.[108] Additionally, we reached excellent enantioselectivities using this compound in the furan cyclopropanation trials (chapter **B 1.2**). Secondly, temperatures lower than room temperature were investigated, as it is a well-known fact in catalysis that lower temperatures can have positive effects on selectivity. Other ligands than those applied before were investigated as well, but, as it will be explained later on, only *tert*-butyl substituted azabox ligands gave good results. Noteworthy, all of the herein reported experiments are not only enantioselective but also highly diastereoselective, forming the *exo*-products exclusively. In none of the cases any hint of *endo*-product formation was observed.

shown in entry 16. Noteworthy, on a 150 mmol scale cyclopropane **103** was obtained in remarkably good 44% yield (59% brsm) and 87% *ee*. Even more important was the fact that **103** was found to crystallize from hexanes, giving a multi-gram quantity of enantiopure (*S,S,S*)-(-)-**103** from this reaction. This strategy enables ready access to this important molecule in good amounts and perfect enantiomeric excess. Besides the effects of our new cyclopropanation conditions on monocyclopropanation product **103**, the fact that double cyclopropanated pyrrole **104** is also formed in significant amounts during this process is interesting. Unfortunately, only very low to no degree of enantioselectivity for the double cyclopropanation product **104** (0-41% *ee*) was found. Until now there is no reasonable explanation for this finding. Nevertheless, possible applications of **104** will be discussed in chapter B 3.

### 1.3.2 Structural investigations of the cyclopropanation products

The absolute configuration of the two cyclopropanation products **103** and **104** were determined by X-ray analysis in combination with chiral HPLC and optical rotation measurements (see experimental section for data). Figure 6 illustrates the structures for monocyclopropane **103** and bicyclop propane **104** obtained by X-ray diffraction.

**Figure 6.** Single crystal X-ray structures of mono-cyclopropanation product (*S,S,S*)-(-)-**103** (left), and double cyclopropanation product **104** (right). (C = grey, H = white, O = red, N = blue).

Especially for double cyclopropanation product **104** the structure shows the strict *exo*-conformation of both cyclopropane rings, resulting in a  $C_2$ -symmetric molecule. The

potential applications of this interesting compound, where six stereogenic centers are formed in a single step from non-chiral *N*-Boc-pyrrole **101**, are discussed in a later part of the present thesis (chapter **B 3.1**). When examining  $^1\text{H-NMR}$  spectra of monocyclopropane **103** one immediately recognizes a strong signal broadening, accompanied by splitting of the corresponding signals. The signal broadening is presumably due to the occurrence of rotational energy barriers of the one, or even both of the *tert*-butyl groups in **103** (restricted rotation around C-N bond due to steric hindrance), leading to the presence of rotational isomers, so-called rotamers. The presence of rotamers can be proven, and distinguished, from the existence of diastereomers by the dynamic behavior of the  $^1\text{H-NMR}$  signals in temperature-dependent NMR experiments.[109-111]

**Figure 7.** Excerpts from the  $^1\text{H-NMR}$  spectra of cyclopropane **103** at 278, 298, and 318 K in  $\text{CDCl}_3$  (600 MHz kryo). The presence of two distinct sets of signals (ratio  $\sim 0.6:0.4$ ) becomes obvious at 278 K. Upon heating the signals melt together, proving the existence of rotamers (rather than diastereomers).

In this case three  $^1\text{H-NMR}$  spectra of **103** were recorded at different temperatures (Figure 7). At low temperature (278 K) it is clearly visible that two distinct sets of signals in a ratio of about 0.6:0.4 appear. This alone does not allow for any conclusions, but if one takes into account that the signals start broadening and melting together at higher temperatures (298 K,

318 K) it is evident that **103** shows strong rotameric behavior, excluding the presence of diastereomers.

### 1.3.3 Synthesis of (*R,R,R*)-(+)-**103**

As already mentioned above, the synthesis of *tert*-butyl-azabox **8** (as well as **9** and **74**) is based on the non-proteinogenic amino acid *tert*-leucine **69**. From an economical point of view, access to the (*R*)-enantiomer of ligand **8** is not advisable (as *D-tert*-leucine is very expensive), and thus alternative strategies toward enantiopure (*R,R,R*)-(+)-**103** need to be employed. Therefore, different ligands based on *D*-configured amino acids were employed for the asymmetric cyclopropanation of *N*-Boc-pyrrole and the results were compared to the already obtained data (table **6**, entries 1-7).

**Table 6.** Asymmetric cyclopropanation of *N*-Boc-pyrrole using *D*-amino acid based ligands.

entry <sup>a)</sup>	ligand	temperature [°C]	yield <b>103</b> [%] <sup>f)</sup>	<i>ee</i> <b>103</b> [%] <sup>g)</sup>	yield <b>104</b> [%] <sup>f)</sup>	<i>ee</i> <b>104</b> [%] <sup>g)</sup>
1 <sup>b)</sup>	<b>68</b>	0	28	53	33	23
2 <sup>c)</sup>	<b>68</b>	0	17	57	19	26

5	<b>61</b>	-10	34	56	27	1
6 <sup>d)</sup>	<b>61</b>	-20	18	41	1.5	5
7 <sup>e)</sup>	( <i>ent</i> )- <b>6</b>	0	30	41	20	5

a) 2.99 mmol (500 mg) *N*-Boc-pyrrole, 1 mol% Cu(OTf)<sub>2</sub>, 2.2 mol% ligand, 1 mol% PhNHNH<sub>2</sub>, 1.5 equiv diazoester, 3 ml DCM; b) defrosting ice-bath; c) cryostat; d) 1.2 equiv diazoester; e) 5.98 mmol (1.00 g) *N*-Boc-pyrrole; f) isolated yield; g) determined by chiral HPLC.

As can be seen from table **6** results are rather poor, leading to a maximum of 57% *ee* for indanyl substituted azabox **68** (entry 2) and 56% *ee* for phenyl-azabox **61** (entry 5). With (*R,R*)-iso-propyl-bisoxazoline (*iPr*-box) (*ent*)-**6** only 41% *ee* could be achieved (entry 7). Interestingly, only the indanyl-substituted azabox ligand **68** led to enantiomerically enriched double cyclopropanation product **104** (entries 1 and 2), while the other ligands yielded more

or less racemic product (entries 4-7). The overall best results in terms of yield and selectivity were found for phenyl derivative **61** at -10 °C with 34% isolated yield and 56% *ee* (entry 5). However, upon repeated recrystallization steps from hexanes it was possible to obtain (*R,R,R*)-(+)-**103** in enantiomerically pure form (HPLC chromatograms shown in figure 9).

**Figure 9.** Analytical HPLC chromatograms for (*S,S,S*)-(-)-**103** (left), rac-(±)-**103** (middle), and (*R,R,R*)-(+)-**103** (right). Phenomenex Lux Cellulose-2, *n*-heptane/*i*PrOH = 98:2, flow = 0.5 ml/min,  $\lambda_{\text{max}}$  = 254 nm ( $t_r$  = 11.3 min (-),  $t_r$  = 19.9 min (+)).

### 1.3.4 Investigations of the stereochemical outcome of the cyclopropanations reactions

Former reports claimed that the asymmetric cyclopropanation of *N*-Boc-pyrrole with methyl diazoacetate leads to inverted stereoselection (giving (*R,R,R*)-(+)-product from *L*-(*S,S,S*)-derived ligands) compared to furan derivatives when using the identical stereochemistry of the ligand ((*S,S,S*)-(-)-product from *L*-(*S,S,S*)-derived ligands).[14, 105, 106] This effect was somehow explained by attractive interactions between the oxygen atom of the furan ring with copper, and in the case of **18** with steric repulsion of the bulky Boc-group in **101**, so that an inverted orientation of the substrate binding to the catalyst was claimed. If this was true it would be a very interesting feature due to the fact that (*S,S,S*)-(-)-**103** was the major product for the same substrate when using *tert*-butyl substituted diazoacetate in the analogous experiments instead (proven by X-ray, chiral HPLC, and optical rotation; see chapters **B 1.3.2** and **D 2**). This would mean that only the size of the incoming ester group should be responsible for a complete inversion of the stereochemical outcome of the product, which is hardly believable. Thus, we aimed to reexamine the stereochemistry of the abovementioned cyclopropanation reaction (which is described in the following). The idea of our strategy was to approach methyl-substituted cyclopropane **18** from two different synthetic sites, whilst comparing the stereochemical outcome and therefore proving, or disproving, the original claim (scheme **15**).

**Scheme 15.** Strategy for the clarification of the stereochemical outcome of the cyclopropanation of *N*-Boc-pyrrole with methyl diazoacetate. Methyl-substituted cyclopropane **18** was synthesized from two different directions in order to clarify matter. **A**: transesterification of **103** using NaOMe; **B**: asymmetric cyclopropanation of **101** using methyl diazoacetate and ligand **8**.

As the absolute configuration of *tert*-butyl-cyclopropane **103** (derived from *L*-(*S,S*)-configured ligands) was reliably established to be (*S,S,S*)-(-)-**103** using X-ray diffraction, chiral HPLC analysis and optical rotation, a transesterification of **103** into the methyl ester should result in a product **18** bearing the identical stereoinformation as its parent compound **103** (in the worst case epimerization of one stereocenter could occur under basic conditions). Several attempts of transforming the *tert*-butyl ester moiety of **103** into a methyl ester failed or only gave poor results.

**Scheme 16.** Transesterification of *tert*-butyl-cyclopropane ester **105** via sodium methoxide by *Fox et al.* [112]

However, a report of *Fox et al.* using sodium methoxide for the transesterification of cyclopropane ester **105** into its methyl derivative **106** (scheme **16**)[112] prompted us to test such conditions for our substrate **103**.

**Scheme 17.** Transesterification of *tert*-butyl-cyclopropane ester **103** via sodium methoxide using the methodology of *Fox et al.*

Thus, **103** was transformed into its methyl derivative using sodium methoxide in refluxing methanol to give **18** in 45% yield (scheme **17**; **A** in scheme **15**).<sup>4</sup> Substrate **103** was chosen with a moderate degree of enantioselectivity (80% *ee*) on purpose in order to facilitate HPLC

<sup>4</sup> Due to the formation of side product **107** from methyl ester **18**, where the Boc-group was transformed into the methyl carbamate, better yields of **18** were not accessible.

analysis. As the transesterification product **18** was obtained with an identical *ee* value as its parent starting material, it can be concluded that no epimerization occurred during the progress of the reaction. Furthermore, the original cyclopropanation of *N*-Boc-pyrrole **101** with methyldiazoacetate was repeated with the aim of comparing the results to those obtained from route **A** (**B** in scheme **15**). In this attempt methylcyclopropane **18** was obtained in 35% yield and 55% enantiomeric excess.<sup>5</sup>

**Figure 8.** Analytical HPLC chromatograms for methyl-substituted cyclopropane **18** from transesterification (**A**), and from cyclopropanation with methyldiazoacetate (**B**). Chiralcel OD-H, *n*-heptane/*i*PrOH = 99:1, flow = 1.0 ml/min,  $\lambda_{\max}$  = 240 nm ( $t_r$  = 5.9 min (-),  $t_r$  = 9.3 min (+)).

When comparing the HPLC chromatograms for the (identical) product of both reactions (**A** and **B**; figure **8**), it becomes apparent that in both cases the very same product was formed by the two orthogonal reactions, namely (*S,S,S*)-(-)-**18**. Furthermore, the newly obtained results were verified by comparison to the original data of *Glos* and it was thus concluded that no stereoinversion occurs while switching the substrates from furan derivatives to *N*-Boc-pyrrole **101**. In contrast, it could be shown that for all investigated cyclopropanation reactions the (*S,S,S*)-(-)-product is forming from *L*-(*S,S*)-derived ligands. On the contrary, the corresponding (*R,R,R*)-(+)-cyclopropanes form when using *D*-(*R,R*)-derived ligands.

<sup>5</sup> The original literature report for this reaction was: 61% yield, 52% *ee* (ref. [105]).

itself toward synaptosomal GABA uptake inhibition.[114] Moreover, homo- $\beta$ -proline **109** and its enantiomers have been widely used as model compounds for structural and functional investigations.[124] Nevertheless, these results only reflect on in vitro activity, which depicts the major disadvantage of compounds like **109**: they do not readily cross the blood-brain-barrier,[125, 126] which renders their potential application as drugs rather meaningless. Therefore, a series of potential pharmaceuticals were developed containing the substructure of **109** bearing a lipophilic moiety (mostly anchored to the endocyclic N-atom), enabling the resulting compounds to cross the blood-brain-barrier and hence showing significantly increased pharmacological activities. One prominent example is the N-modified analogue of homo- $\beta$ -proline SKF 100561 (**110**, figure **11**), which shows significantly increased GABA uptake inhibition ( $IC_{50} = 0.12 \mu M$  compared to  $1.5 \mu M$  of the parent amino acid **109**). Furthermore, it displayed anticonvulsant activity upon oral or intraperitoneal administration to rats.[127-129] In addition, **110** was shown to exhibit antitussive properties,[130] whereas in a different study it was presented that **110** potentially counteracts the enhancing effect of GABA on dopamine release in rat brain, allowing for the conclusion for coexistence of transporters of GABA and dopamine.[131] Reflecting on the remarkable properties of this molecule, *Young* and co-workers identified it to be a potent histamine  $H_1$ -receptor antagonist as well.[132] In 2001, homo- $\beta$ -proline derivative **111** was reported as the most potent compound in a series of 33 potential GABA uptake inhibitors ( $IC_{50} = 51 \text{ nM}$ ), however, its in vivo anticonvulsant properties were rather poor.[117] Figure **11** gives an exemplary overview of some recent pharmacologically active compounds containing **109** as structural motif.

**Figure 11.** Chemical structures of selected examples of derivatives of homo- $\beta$ -proline that were designed for pharmaceutical purposes (core structure of **109** highlighted in red).

Furthermore, a couple of very recent patents deal with pharmaceutical compounds that incorporate **109** as pharmacophore in a certain manner (figure 11). While derivatives of type **112** act as P2Y<sub>12</sub> receptor antagonists[133] and therefore display antitrombotic activity, **115** was prepared as a potential prostaglandine D2 receptor antagonist.[134] On the other hand, **113** acts as a protein kinase inhibitor (both isomers of **109** were incorporated),[135] and **114** as an inhibitor of leukotriene production (inhibitor of leukotriene A<sub>4</sub> hydrolase).[136, 137] Besides the presented examples in figure 11, many more substances containing units of either racemic or enantiopure **109** in their core structure have been reported recently. Moreover, both enantiomers of 3-pyrrolidineacetic acid **109** are not only biologically active by themselves, but also display a key structural element in a broad variety of natural products (figure 12).

**Figure 12.** Chemical structures of some structurally related natural products (core structure of **109** highlighted in red).[138-140]

The examples shown in figure **12** (**116-119**) belong to the family of kainoid amino acids that are structurally based on glutamic acid and display significant biological effects, e.g. insecticidal,[141, 142] anthelmintic,[143-146] and (most importantly) neuroexcitatory properties.[147-151] The compounds presented in figures **11** and **12** clearly demonstrate the importance of homo- $\beta$ -proline, thus making it an interesting target molecule.

### 2.1.2 Literature syntheses of homo- $\beta$ -proline **109**

Based on our positive results from the asymmetric cyclopropanation of *N*-Boc-pyrrole, we aimed to develop a more efficient synthesis route for (*S*)-3-pyrrolidineacetic acid ((*S*)-(+)-**109**). The following chapter gives a brief overview of the strategies for the synthesis of **109** reported so far. While access to 2-substituted derivatives of pyrrolidine is pretty straightforward (most syntheses start from *L*- or *D*-proline and/or derivatives thereof), methods for the preparation of 3-substituted analogues, especially in enantiomerically pure form, are limited. So far there have been eight synthetic routes reported in literature for either racemic or enantiopure homo- $\beta$ -proline, with only one of them being enantioselective. The first synthesis of racemic ( $\pm$ )-**109** was reported by *Schaumburg et al.* in 1981, who synthesized **109** in 4% yield over 7 steps starting from glycine ethyl ester hydrochloride (**120**).[118] Key steps in their synthesis were a *Dieckmann* condensation to establish the pyrrolidine skeleton and a *Knoevenagel* condensation of **121** with cyanoacetic acid for the introduction of the side chain in **122** (scheme **18**).

**Scheme 18.** First racemic synthesis of ( $\pm$ )-**109** by *Schaumburg et al.*[118]

The first non-racemic synthesis of (*R*)-(-)-**109** and (*S*)-(+)-**109** was reported in 1990 by *Krogsgaard-Larsen et al.*[114] Based on the addition-cyclization reaction of itaconic acid **123** with (*R*)-1-phenylethylamine and subsequent separation of the resulting diastereomers **124a**

and **124b** via preparative HPLC, they were able to obtain both enantiomers of **109** in 8 steps each and ~ 6% overall yield (scheme 19).<sup>7</sup>

**Scheme 19.** First synthesis of (*S*)-(+)- and (*R*)-(-)-homo- $\beta$ -proline from itaconic acid **123** by *Krogsgaard-Larsen et al.*[114]

In 1996, *Coldham* and *Huften* reported a very short and efficient synthesis of racemic homo- $\beta$ -proline based on the cyclization reaction of stannane **127** (scheme 20).[152] Hereby a tin-lithium exchange of stannane **127**, followed by an anionic cyclization reaction and subsequent trapping with an electrophile, represents the crucial step to yield **128** (interestingly, the *N*-benzyl group was replaced by *N*-CO<sub>2</sub>Et during this reaction).

**Scheme 20.** Synthesis of racemic ( $\pm$ )-**109** according to *Coldham and Huften*. [152]

Within four synthetic steps they were able to obtain ( $\pm$ )-**109** from commercially available 4-bromobut-1-ene **125** in 15-27% yield (the authors did not give a yield for the first step; from literature it is recognized that **126** can be prepared by the referred strategy in 52-93% yield). However, based on the fact that organotin reagents are not too desirable nowadays, their synthesis strategy may not be of great importance for current studies. In a similar approach to the one reported by *Krogsgaard-Larsen et al.*, [114] *Orena* and co-workers developed several intramolecular cyclization reactions for the generation of the pyrrolidine ring with an appropriate substitution pattern.[153-155] Based on cyclization product **131**, which was obtained in 75% yield and a diastereomeric ratio of 80:20 from **130**, both enantiomers of homo- $\beta$ -proline were synthesized in 7 steps each (scheme 21). In this way they were able to obtain (*S*)-(+)-**109** in 11% and (*R*)-(-)-**109** in 3% yield.

<sup>7</sup> The authors did not provide a yield for the last synthetic step for (*S*)-(+)-**109**.

**Scheme 21.** Synthesis of (*S*)-(+)- and (*R*)-(-)-homo- $\beta$ -proline by *Orena et al.*

In a slightly older communication, *Orena et al.* presented a formal synthesis of **109** with a Mn(III)-mediated intramolecular cyclization reaction as the key step. By this strategy they were able to prepare synthetic intermediate **135**, the same that was used for the synthesis of **109** by *Krogsgaard-Larsen et al.*[114] from chiral amine **132** in 6 steps and 17% yield (scheme **22**).[153]

**Scheme 22.** Formal synthesis of (*S*)-(+)-**109** through Mn(III)-mediated intramolecular cyclization of **133** by *Orena et al.*

On the way to conformationally restricted NO synthase inhibitors, *Eustache* and co-workers synthesized (*S*)-(+)-homo- $\beta$ -proline **109** from intermediate **136** (obtained from aspartic acid)[156] in order to determine the absolute configuration of their compounds (Scheme **23**).[157] Key steps of the synthesis were the lactamization of a nitro-*Michael*-adduct, followed by transformation into the corresponding thiolactam by *Lawesson's reagent* (including chromatographic separation of diastereomers), and subsequent desulfurization in order to establish the pyrrolidine ring system. Additionally, besides some protection/deprotection steps, a desamination-decarboxylation sequence had to be carried out to finally yield **109** in 9 steps and 5% yield starting from **136**.

**Scheme 23.** Synthesis of (S)-(+)-homo- $\beta$ -proline **109** from **136** by *Eustache et al.*[157]

In the same year, *Gmeiner et al.* presented an efficient 11 step synthesis of **109** starting from (S)-aspartic acid **139** (scheme **24**).[158] In this chiral pool approach, 1,4-bis-electrophile **140** was rearranged to **141** through an aziridinium ion (not shown) and subsequently cyclized to form the pyrrolidine core. Inversion of the stereocenter by  $S_N2$  type substitution with diethylmalonate, followed by a decarboxylation gave rise to (R)-(-)-**109** in an overall yield of 23%. Importantly, (R)-aspartic acid could be applied as well for the synthesis of the enantiomeric (S)-(+)-**109**.

**Scheme 24.** Synthesis of (R)-(-)-homo- $\beta$ -proline **109** from aspartic acid **139** by *Gmeiner et al.*[158]

In 2004, *Felluga* and co-workers[159] reported a chemoenzymatic synthesis of both enantiomers of homo- $\beta$ -proline based on the desymmetrization reaction of prochiral nitrodiester **144** (scheme **25**).[159]

**Scheme 25.** Synthesis of both enantiomers of homo- $\beta$ -proline via enzymatic desymmetrization of prochiral nitrodiester **144** according to *Felluga et al.*[159]

For the selective saponification of only one of the two ester groups in **144**, two different enzymes had to be applied, namely porcine pancreatic lipase (PPL) for the synthesis of

**Scheme 27.** Enantioselective synthesis of **103** from pyrrole **50**.

Based on the experiments from chapter **B 1.3.1** it is well-known that bicycle **103** can be prepared in moderate yield with full enantiocontrol (scheme **27**). Now there are plenty of opportunities of how to apply this highly functionalized cyclopropane for further synthetic ventures. Obviously, the simplest modification of **103** would be the hydrogenation of the enecarbamate double bond to yield the fully saturated system **149**. This can be carried out efficiently using standard conditions (hydrogen, palladium/charcoal) in order to yield **149** in satisfying 85% yield (scheme **28**).

**Scheme 28.** Hydrogenation of bicyclic enecarbamate **103** using standard conditions.

However, an alternative to the conventional hydrogenation with hydrogen and palladium/charcoal would be the so-called ionic hydrogenation, which has been shown to work efficiently for enamides and enecarbamates.[161-164] In this methodology, the substrate is successively activated by an acidic compound (*Brønsted* or *Lewis* acids) and then reduced by the addition of hydride, mostly from silanes as hydride source. In order to test whether an ionic hydrogenation might produce even higher yields of **149** cyclopropane **103** was treated with trifluoroacetic acid (TFA) and triethylsilane at room temperature. Indeed, chemoselective ionic hydrogenation of the enecarbamate double bond of **103** occurred, accompanied by ring-opening of the donor-acceptor substituted cyclopropane moiety, to give a significant amount of by-product **150** (scheme **29**). After six hours at ambient temperature 33% of hydrogenation product **149** and 23% of ring-opened compound **150** were isolated.

**Scheme 29.** Ionic hydrogenation of **103** using trifluoroacetic acid in combination with triethylsilane.

This observation can be explained by the occurrence of the desired ionic hydrogenation step of the double bond followed by an acid-catalyzed ring-opening reaction (also traceable by TLC). The corresponding iminium ion should then be trapped by hydride in order to provide **150**. Acid-catalyzed cyclopropane opening is a well-known process in synthetic organic chemistry and innumerable examples have been shown in literature.[165-167] The absolute configuration of ring-opened compound **150** was proven by X-ray analysis (figure 13) in combination with optical rotation and chiral HPLC analysis (see experimental section).

**Figure 13.** Single crystal X-ray structure of double protected 3-pyrrolidineacetic acid **150** (*left*), and chemical structure of **150** (*right*).

The fact that cyclopropane **149** can be opened readily by the application of acid led us to the idea of making use of it in terms of a total synthesis of homo- $\beta$ -proline **109** (see chapter **B 2.1.1**). This seems pretty straightforward from **150** (which can be seen as a double protected derivative of **109**), if one can find a way of optimizing the abovementioned reaction to some extent. However, the occurrence of another side-product of the ionic hydrogenation reaction of **103** then attracted our attention. Every time enecarbamate **103** was treated with TFA, two

new spots appeared on TLC. Thus, we examined the chemical behavior of cyclopropane **103** upon treatment with TFA in order to identify these side-products. Interestingly it could be shown that **103** dimerizes upon treatment with TFA to form two diastereomers **151** in a ratio of ~ 3:1 (scheme **30**).

**Scheme 30.** Concentration-dependent acid-catalyzed dimerization of enecarbamate **103** (combined yields for both diastereomers).

Logically, the reaction turned out to be concentration dependent, giving 42% yield (combined yield of both diastereomers) at a concentration of ~ 0.1 M, and 55% at ~ 0.4 M. In this case the yields could not be optimized due to partial decomposition occurring after prolonged reaction time, which makes sense since dimer **151** contains four *tert*-butyl groups that are regularly cleaved by TFA.[168] The formation of dimer **151** might seem exotic at first, however, it can be explained by having a closer look at the potential mechanism of dimerization for this type of enecarbamate, which was concluded on the basis of the general reactivity pattern of enamides and enecarbamates,[169-171] as well as extensive spectroscopic analyses of the products (scheme **31**).

**Scheme 31.** General reactivity pattern of enamides and enecarbamates (*upper part*), and the proposed mechanism for the acid-catalyzed dimerization of enecarbamate **103**, along with the chemical structure of Peramivir™ **157** (1,3-diamino moiety highlighted in red).

In general, enamides (and enecarbamates) exhibit an ambivalent reactivity (two opposing reaction pathways), meaning that they can undergo reactions with both electrophiles and nucleophiles. Generally enamides of type **152** react as nucleophiles which attack a suitable electrophile ( $E^+$ ), generating an iminium ion **153** (and **155**) that is then trapped by a nucleophile ( $Nu^-$ ) to yield a double functionalized amide or carbamate **154** (scheme **31**, *upper part*). When having a look on the mechanism of dimerization of **103** it becomes obvious that first the protonation of **103** turns it into the iminium species **155** that acts as the electrophile for the dimer formation. A second molecule of **103** then reacts as nucleophile and attacks the iminium ion **155** to form the dimer **156**. In the final step  $H^+$  is eliminated to close the catalytic cycle and yield dimer **151** as product (scheme **31**, *lower part*). Dimer **151** could potentially be of synthetic interest as it bears a 1,3-diamine moiety in its core structure (highlighted in scheme **31**). Optically active 1,3-diamines are valuable targets, as they represent key structural units in many natural products.[172, 173] Moreover, they can be used as chiral auxiliaries and ligands,[174, 175] catalysts in asymmetric synthesis,[176] as well as pharamcophores in medicinal chemistry.[177-181] One prominent example is the commercial drug Peramivir™ **157**, which exhibits potent activity against influenza viruses (scheme

31).[182, 183] Furthermore, efficient synthetic strategies toward enantiopure 1,3-diamines are rather limited until now.[184-188]

Coming back to the original purpose to investigate **103** as a promising precursor for the synthesis of homo- $\beta$ -proline **109**, one has to bear in mind that side reactions like the dimerization mentioned before are rather deleterious for our synthetic endeavor. As already mentioned it is rather likely that the ring-opened product **150** is formed from the hydrogenated compound **149** during the course of the reaction (traceable by TLC). Thus, one can envision carrying out the synthesis in a two-step manner, starting with hydrogenation of the double bond in **103** with conventional methods ( $H_2$ , Pd/C) followed by acid catalyzed ring opening. In this way side reactions of the enamide can be suppressed and **150** should be accessible in improved yields. Scheme **32** presents the two-step approach for the synthesis of **150**.

**Scheme 32.** Two-step synthesis approach of ring-opened product **150** from cyclopropane **103**.

From hydrogenation product **149**, homo- $\beta$ -proline derivative **150** was obtained in 50% yield. In this case, the yield could not be further optimized as at a certain point new very polar spots occurred on TLC, which might be assigned to partly and fully deprotected **150** (**109**). This observation again led us to the idea to use this feature in terms of directly converting hydrogenation product **149** into homo- $\beta$ -proline (or its TFA salt). As the ionic hydrogenation/cyclopropane opening conditions already contain TFA, an in situ deprotection of the Boc-group and the *tert*-butyl ester seems plausible. Even a one-step procedure starting from cyclopropane **103**, should in principle be possible; however the occurrence of side-products might influence the outcome of the reaction and also hamper the final purification of the desired polar amino acid **109**.

**Scheme 33.** Synthesis of (*S*)-(+)-homo- $\beta$ -proline **109** from **149**.

When **149** was treated with TFA and triethylsilane for 72 h at room temperature, the TFA salt of **109** was obtained, that was then transformed into the free amino acid **109** by the use of an acidic ion-exchange resin and elution with aqueous ammonia. (*S*)-(+)-homo- $\beta$ -proline (*S*)-(+)-**109** was obtained in quantitative yield from cyclopropane **149**. Spectroscopic data of (*S*)-(+)-**109** were in agreement with literature data.[114, 155, 158-160] However, the optical rotation value of **109** was slightly lower than reported before (+7.7 ( $c = 1$ , H<sub>2</sub>O) compared to +9.6 ( $c = 1$ , H<sub>2</sub>O)[114]). Upon investigation of the stereochemical outcome of the TFA mediated cyclopropane opening from **149** to **150**, we found a significant degree of epimerization of the stereocenter in **150**, and the enantiomeric excess was reduced from >99% *ee* for **149** to 73% *ee* for **150** (determined by chiral HPLC, see **E 2**). Further studies for achieving the synthesis of **109** from **103** without loss in stereoinformation are currently ongoing in the *Reiser* group. Nevertheless, it should also be noted that a synthesis of the enantiomeric (*R*)-(-)-**109** from (*R,R,R*)-(+)-**103** should be straightforward, following the very same synthetic sequence developed for (*S*)-(+)-**109**.

Upon a closer look into literature, it seemed as if the use of **109** as a pharmacophore is rather limited, even though it is obvious that the compound itself and its derivatives are in many cases among the most potent derivatives tested.[117, 119, 122, 127, 131, 189] This fact might be due to the rather displeasing synthesis strategies for **109** thus far published. However, with our new methodology it is possible to get relatively simple access to either racemic or enantioenriched homo- $\beta$ -proline, which can then be used as a key building block for the preparation of new (and established) pharmaceutically relevant compounds. Furthermore, it may stimulate further investigations with the involvement of **109** as pharmacophore, as before practical access was rather limited. In summary we have developed a short and efficient methodology for the preparation of either enantiomer of 3-pyrrolidineacetic acid (homo- $\beta$ -proline) **109** based on the enantioselective cyclopropanation of *N*-Boc-pyrrole **101**. The abovementioned cyclopropanation can be carried out on a 150 mmol scale, thus giving rise to

a multigram quantity of enantiopure **103**. In as few as three steps, (*S*)-(+)-**109** (or ( $\pm$ )-**109**/(*R*)-(-)-**109**) can be prepared in 37% yield from *N*-Boc-pyrrole, giving facile access to such biologically and pharmaceutically relevant compounds.

## 2.2 Further functionalization approaches of monocyclopropane **103**

It was demonstrated that cyclopropane **103** reacts efficiently with nucleophiles under acidic conditions (see chapter **B 2.1.3**). After discovery of such a mode of reactivity it was obvious to apply this methodology to other, more challenging nucleophiles besides the enamide (enecarbamate) itself, and the hydride ion (products **149** and **151**), that might lead to an even higher degree of functionalization of this interesting building block.

The *Ugi* multi-component reaction (MCR) is an extremely powerful method for the construction of rather complex molecules that has been applied extensively in organic synthesis and in particular for the generation of large compound libraries.[190]

**Scheme 34.** General scheme for *Ugi* four-component reactions (different building blocks/subunits color coded).

In general, four components are used in this reaction. At first, an imine (or iminium) species is formed by an amine **159** and a carbonyl compound **160** (aldehyde or ketone). However, this first intermediate can also be preformed. Then an isocyanide (isonitrile) **161** attacks the imine and is instantly trapped by the carboxylate **158**. In the last step, an *O,N*-acyl shift occurs to yield the final products of type **162** (Scheme **34**).

A recent publication of *Nenajdenko et al.* attracted our attention,[191] where they presented a MCR with cyclic imines, isocyanides, and organic acids, giving rise to functionalized pyrrolidines in moderate to excellent yields (Scheme **35**).

**Table 7.** Attempts for the TFA initiated *Ugi*-type functionalization of cyclopropane **103**.<sup>9</sup>

As can be quickly recognized from table **7**, the proposed reaction worked efficiently for only one substrate, namely *tert*-butyl-isonitrile (entry 2). Here, the two diastereomeric addition products were formed in 69% combined yield and a diastereomeric ratio of ~ 3:1. Detailed analysis of the products is described in a later part of this chapter. Interestingly, for all substrates besides 4-methyl-substituted isonitrile (entry 10), product formation could be

<sup>9</sup> Aromatic isonitriles of entries 7-10 were provided by M. Knorn.

identified by LC-MS, however, in most cases only in trace amounts. When comparing entries 1 and 2, one might expect that the excess of isocyanide might have favored the outcome of the reaction (1.2 equiv vs. 10 equiv R-NC). On the other hand, the cyclohexyl-substituted isocyanide did not lead to the formation of significant amounts of product while employing the same conditions as in entry 2 (entry 4). This leads to the suspicion that hydrolysis of the isocyanide may not be the limiting factor. For the 2,4-dimethoxy-substituted residue also a minor amount of TFA acylated product **171** could be identified (entry 8), whereas no acylation product was found for the other substrates. Due to a lack of suitable  $^1\text{H-NMR}$  signals for integration, the values for the diastereomeric ratio of the obtained addition products were determined by integration of LC-MS signals, and should therefore be taken as a rough estimation rather than exact values. Nevertheless, when comparing the data of entry 2 of table 7 with the isolated amounts of diastereomers of **165a** and **165b** it becomes evident that the ratio, at least for this reaction, is quite similar. However, due to limited access to non-commercial isocyanides, no further efforts for optimizing the reaction conditions were carried out. As *tert*-butyl-isocyanide was the only of the investigated isocyanide derivatives that worked properly for this kind of reaction, we investigated the structure of the resulting diastereomeric compounds in more detail (table 7, entry 2; scheme 36).

**Scheme 36.** Synthesis of *tert*-butyl substituted addition products **165a** and **165b** from cyclopropane **103** and *tert*-butyl isocyanide.

The two diastereoisomers **165a** and **165b** that were formed in a ratio of  $\sim 3:1$  could be separated via flash chromatography, and the orientation of the newly formed stereocenter was unambiguously assigned using NOE experiments (minor diastereomer **165b**). The therefore required NMR spectra had to be carried out at low temperature (223 K) because of strong rotameric behavior of **165a** and **165b** leading to significantly broadened signals at ambient temperature. Figure 14 illustrates these observations. As expected, the major product was the one with the new amide substituent in *exo*-position in regard of the cyclopropane ring (**165a**).

**Figure 14.**  $^1\text{H-NMR}$  spectra of the  $\alpha\text{-CH}$  (in regard of N) region of minor diastereomer **165b** at 223, 300 and 323 K in  $\text{CDCl}_3$  (400 MHz). The presence of rotamers (ratio  $\sim 0.6:0.4$ ) becomes obvious at 223 K.

In addition to the functionalizations via Ugi-type of mechanism, it was as well tested to directly add 1,3,5-trimethoxybenzene as a nucleophile to the enecarbamate **103** in an electrophilic aromatic substitution reaction (scheme 37).

**Scheme 37.** Synthesis of functionalized derivative **172** from cyclopropane **103**.

Scheme 37 shows that enamide **103** can be functionalized via electrophilic aromatic substitution as well. The rather low yields may be explained by the high steric demand of both reactants. Nevertheless, almost any type of nucleophile may be employed for the functionalization of **103**, giving rise to a great variety of functionalities on this highly substituted pyrrolidine scaffold.

### 3 Transformations of double cyclopropanated pyrrole **104**

#### 3.1 Introduction

As doubly cyclopropanated pyrrole **104** was accumulating in significant amounts during the cyclopropanation reactions discussed before (chapter **B 1.3**), we were hence considering possible applications for it. It was noted before that **104** exhibits  $C_2$ -symmetry, which makes it an interesting compound for further derivatizations (figure **15**).

**Figure 15.** X-ray structure of bis-cyclopropane **104** from front (*left*) and top view (*right*), illustrating the  $C_2$ -symmetrical arrangement of the tricyclic core structure (all hydrogen atoms – except for the cyclopropane hydrogens – as well as the Boc protecting group at nitrogen (*blue*) are omitted for the sake of clarity; dotted line demonstrating the hypothetical  $C_2$ -symmetry axis).

In the following chapters the investigated attempts for the transformation of tricycle **104** into potentially biologically active pyrrolidine derivatives, as well as into a chiral  $C_2$ -symmetrical ligand for metal catalysts are described. The initial task in this part of the thesis was to find a suitable way of opening the two cyclopropane rings in **104**, in order to give  $C_2$ -symmetrical pyrrolidines of type **174** (scheme **38**).<sup>[194-198]</sup> This should be possible in principle, since it is well-known that donor-acceptor (DA) substituted cyclopropanes like **104** can be opened selectively by cleaving the bond in between the donor (D) and the acceptor (A).<sup>[165, 199, 200]</sup> As an important fact to bear in mind, *Diederich* and co-workers could show that  $C_2$ -symmetrical pyrrolidines like **173** exhibit remarkable activity as inhibitors of HIV-1 protease,<sup>[201]</sup> thus making such molecules highly demanded (scheme **38**).

**Scheme 38.** General structure of potent HIV-1 protease inhibitors, containing a 3,4-disubstituted  $C_2$ -symmetrical pyrrolidine skeleton **173**, along with potentially accessible compounds **174** from bis-cyclopropane **104** that are structurally related to **173**.

With this in mind, we started a series of experiments for the selective ring-opening of the DA-cyclopropane bonds in tricycle **104** (or derivatives thereof) by using orthogonal strategies.

### 3.2 Opening of donor-acceptor substituted bis-cyclopropanes according to *Werz et al.*

From the group of *Werz* it is known that furan based bis-cyclopropane dialdehydes like **176** can be converted into annelated oligoacetals by collapse of the highly unstable *push-pull* cyclopropane system **176**.<sup>[202, 203]</sup> Within a repeated three-step sequence of double cyclopropanation, reduction and oxidation of furan **35**, all-*anti*-oligoacetals up to the nonamer **175** have been constructed and their structures were thoroughly analyzed by means of X-ray crystallography and DFT calculations (scheme **39**). It was shown that oxidation by 2-iodoxybenzoic acid (IBX)<sup>[204]</sup> in dimethylsulfoxide (DMSO) was a proper method for oxidizing the bis-cyclopropane diol moiety, and thus inducing cyclopropane ring opening, followed by a ring-closure reaction to form cyclic enol ether compounds like **177**.

**Scheme 39.** Preparation of all-*anti*-fused oligoacetals **175** by a repeated three-step sequence starting from furan **35**, reported by *Werz et al.* (left). Key step is a ring enlargement reaction from tricyclic bis-cyclopropane aldehyde **176** to bis-enol ether **177** (right).

As until then *Werz* and co-workers had only reported such kind of transformations for furan derivatives, it seemed as an attractive strategy to us to envision pyrrolidine based compounds

of that same type (bearing a nitrogen atom in the central ring, instead of oxygen). Thus reduction of the two *tert*-butyl ester moieties of **104** by lithium aluminum hydride (LAH) was straightforward, leading to diol **178** in 95% yield (scheme 40).

**Scheme 40.** Synthesis of  $C_2$ -symmetric tricyclic compound **179** from diester **104**, attempted deprotection and proposed mechanism of the rearrangement from **178** to **179**. However, calculations from *Werz et al.* suggested that – at least for furan derivatives – the ring enlargement step might occur in a concerted manner.

The second step was the abovementioned oxidation using IBX in DMSO, which led to tricyclic molecule **179** in satisfying 52% yield. Unfortunately, soon after having **179** in hand, the *Werz* group brought out another publication, showing the synthesis of the very same compound (and some derivatives), however, in somewhat inferior yield (42%).<sup>[205]</sup> An attempt to deprotect the N-atom in **179** in order to yield a potential  $C_2$ -symmetrical ligand for metal complexes **180**, failed due to decomposition of the starting material. Another idea for turning this into something useful was to investigate the cyclopropane opening behavior in a rearrangement reaction.

**Scheme 41.** Proposed mechanism for a base induced rearrangement of acetylated cyclopropane derivatives **184** for the formation of compounds like **186**.

It was thought that diol **178** could be protected by acetyl (Ac) groups and further undergo a rearrangement, which would open the cyclopropane bonds upon enolization with a suitable base. This would lead to interesting compounds like **186**. Scheme 41 depicts the proposed strategy for this idea. A protocol of *Pietruszka et al.* was applied successfully for the

acetylation of diol **178**,[206] giving rise to double acetylated pyrrole **187** in 91% yield within ten minutes reaction time (scheme 42).

**Scheme 42.** Acetylation of diol **178** and unsuccessful attempt for the base-induced rearrangement of **187**.

However, the crucial step in this approach failed and only unreacted starting material, along with minor amounts of partially hydrolyzed **187**, were isolated. With the recent publication of *Werz et al.* in mind, and the fact that the subsequent trials were not successful, we turned our attention to other strategies for the opening of the DA-cyclopropane bonds of **104**.

### 3.3 Hydrogenolysis of donor-acceptor substituted cyclopropanes

Hydrogenolysis of carbon-carbon bonds is a well-known process in chemistry. Especially small rings with a high degree of ring strain, e.g. cyclobutanes or cyclopropanes, are somewhat prone to undergo ring opening reactions. Due to their intrinsic ring strain, catalytic opening of small rings by hydrogenolysis can be carried out at ‘rather mild’ conditions. Indeed, first examples go back to the early 20<sup>th</sup> century when *Willstätter* and *Bruce* first hydrogenated cyclopropane **189** and cyclobutane **191** to their corresponding aliphatic alkanes **190** and **192** using a nickel catalyst (scheme 43).[207] Since then, several examples have appeared in literature revealing that this process is a valuable tool for synthetic chemistry. Scheme 43 presents some outstanding literature precedents for such reactions.

**Scheme 43.** Literature precedents for the catalytic hydrogenolysis of cyclopropane moieties (bonds to be cleaved are highlighted in red).

*De Meijere* and co-workers presented the catalytic hydrogenolysis of multiple *spiro*-annulated cyclopropanes **193**, using one atmosphere of hydrogen gas on a platinum(IV)-oxid catalyst. These highly strained compounds were shown to react smoothly even at low temperatures to form products like **194** (scheme 43).[208] Another interesting example is the catalytic hydrogenolysis of DA-cyclopropane **195** with palladium on charcoal at slightly elevated pressures to form **196** and **197**, reported by *Adams and Belley*.[209]

Therefore, it was tested whether such an approach could also be adapted for our doubly cyclopropanated pyrrole derivative **104**. It seems plausible, that in our case, the bond between the donor and the acceptor should be the one to be cleaved most readily (red bonds in **104**, scheme 44), due to the known fact that these bonds are typically the longest, and thus weakest, in such compounds.[210] In theory, one could obtain 3,4-disubstituted  $C_2$ -symmetric pyrrolidines **199** in one step via this method. As already mentioned before, derivatives of such compounds exhibit significant biological properties and hence are reasonable target structures.

**Scheme 44.** Theoretical scheme for the hydrogenolysis of DA-cyclopropane **104** and the expected products for this type of transformation **198** and **199** (bonds presumably cleaved are given in red; A = acceptor, D = donor).

A first approach for screening several different catalyst systems was conducted using the *ThalesNano H-Cube Pro*<sup>TM</sup>, a continuous flow system for hydrogenation reactions that allows for rapid screening of reaction conditions. Therefore, compound **104** was dissolved in methanol, passed through the reactor for one cycle (at variable conditions, e.g. temperature,

pressure, flow). The crude reaction mixture was analyzed by  $^1\text{H-NMR}$  spectroscopy. Figure 16 illustrates the experimental setup used for these attempts.

**Figure 16.** Illustration of the reaction setup for catalyst screening using the *ThalesNano H-Cube Pro*<sup>TM</sup>. **A:** solvent; **B:** substrate in solvent (MeOH); **C:** HPLC pump; **D:** control element, display for adjusting and monitoring reaction parameters (temperature, pressure, flow, etc.); **E:** reaction chamber containing catalyst cartridge (incl. heating block); **F:** waste drain; **G:** recovered product mixture in solvent.

The obtained results of our screening attempts for the catalytic hydrogenolysis of **104** are summarized in table 8. It could be shown that the major product of such experiments was none of the expected products (**198** or **199**; scheme 44), but unsaturated derivative **200**. A discussion about the possible way of formation for **200** will be given in a later part of this chapter (scheme 45). Looking at entries 1-6 of table 8, one immediately realizes that neither 10% Pd/C, nor 5% Pt/C were suitable catalysts for the investigated transformation, as there was absolutely no conversion of starting material observable after one cycle (even at temperatures and hydrogen gas pressures of up to 80 °C and 80 bar, respectively). However, when using 5% Rh/C, significant amounts of product (< 10%) could be detected in the crude NMR spectra (40 °C, 40 bar; entry 7, as well as at 60 °C, 60 bar; entry 8). Surprisingly, when forcing the conditions up to 80 °C, 80 bar with the same catalyst system, no conversion of starting material was observed (entry 9).

**Table 8.** Screening of reaction conditions for the catalytic hydrogenolysis of **104** under flow conditions using the *H-Cube*<sup>TM</sup>.

entry <sup>a)</sup>	catalyst	temperature [°C]	H <sub>2</sub> pressure [bar]	conversion <sup>e)</sup>
1	Pd/C (10%)	50	40	0
2	Pd/C (10%)	60	60	0
3	Pd/C (10%)	80	80	0
4	Pt/C (5%)	40	40	0
5	Pt/C (5%)	60	60	0
6	Pt/C (5%)	80	80	0
7	Rh/C (5%)	40	40	4.8
8	Rh/C (5%)	60	60	8.5
9	Rh/C (5%)	80	80	0
10 <sup>b)</sup>	Rh/C (5%)	60	60	0
11 <sup>c)</sup>	Rh/C (5%)	40	40	8.3
12 <sup>c)</sup>	Rh/C (5%)	60	60	9.7
13 <sup>c)</sup>	Rh/C (5%)	60	80	0
14	Rh/C (5%)	50	50	0
15	Rh/C (5%)	60	60	0
16 <sup>d)</sup>	Rh/C (5%)	60	60	0

a) 0.05 mmol (20 mg) **104**, 4 ml MeOH; b) flow = 0.3 ml/min, 4 consecutive runs through system; c) fresh catalyst cartridge; d) flow = 0.3 ml/min; e) determined by <sup>1</sup>H-NMR of the crude reaction mixture without internal standard.

In order to enrich the amount of product for isolation and purification purposes, there are two obvious options: 1) reducing the flow rate, and 2) raising the amount of consecutive runs through the system in order to increase contact time of the reaction mixture with the catalyst cartridge (reaction chamber; **E** in figure **16**). Hence, the flow rate was set to a minimum value of 0.3 ml/min and the reaction mixture was passed through the system for four consecutive cycles at conditions that gave superior conversion before (60 °C, 60 bar; entry 10). But again no conversion was detectable, which made us curious, as this result did not make any sense at all. Surprisingly, when using a fresh catalyst cartridge of Rh/C (5%), product formation was observed again (entries 11 and 12), indicating a possible, but rather unlikely deactivation of the catalyst system. Unfortunately, follow-up experiments again failed, leading to zero conversion (entries 13-16). This led us to resign from this approach and to rather focus on other methods. The product formed during these attempts could unfortunately not be isolated and fully characterized, due to the limited scale of the experiments and the almost identical  $R_f$  values of **200** and the starting material **104**. However, figure **17** illustrates the strategy for its

identification by comparison of  $^1\text{H-NMR}$  spectra. Mass spectrometry did, in this case, not help, as the starting material and the product would have identical molar masses.

**Figure 17.** Identification of ring-opened product **200** (blue), by comparison of the  $^1\text{H-NMR}$  spectra of the crude reaction mixture with those for starting material **104** (red), and structurally related mono-cyclopropane **103** (green). Separation of the crude mixture was not possible and the molar masses of starting material and product are identical (rearrangement).

In scheme **45**, a plausible mechanism for the formation of the obtained product is depicted. Starting from acid-mediated opening of the DA-cyclopropane bond and tautomerism of the enol moiety to the corresponding ester, intermediary iminium species **202** can then react via two orthogonal pathways: 1) Addition of hydride to the iminium ion would lead to an overall hydrogenolysis process (red in scheme **45**), whereas 2) elimination of a proton in  $\beta$ -position would lead to the product of an acid-catalyzed rearrangement process (blue in scheme **45**).

**Scheme 45.** Plausible mechanism for the above investigated transformation of bis-cyclopropane **104**. In principle two pathways can be envisioned, leading to different types of products. The classical strategy of hydrogenolysis (*red*) would lead to a product like **198**, while an acid-catalyzed rearrangement (*blue*) would give rise to **200**.

Batch experiments were conducted in the following, as it was shown that catalyst deactivation was assumed to be a critical issue in the *H-Cube*<sup>TM</sup> experiments (table **8**). Thus, in table **9** we tried to reproduce the results from the abovementioned flow experiments, and to accumulate product amount for complete characterization. To our surprise, we found that in these reactions not the unsaturated pyrrolidine **200** but ring-opened methanol adducts of type **203** and **204** were formed, probably due to trapping of the intermediary iminium ion **202** by a molecule of methanol.

**Table 9.** Attempts for the hydrogenolytic cleavage of cyclopropane **104** under batch conditions.

entry <sup>a)</sup>	H <sub>2</sub> pressure [bar]	temperature [°C]	additive	time [d]	conversion <sup>f)</sup>
1	1	25	-	2	0
2 <sup>b)</sup>	60	60	-	1	<i>traces</i>
3	1	25	10% HOAc (v/v)	19	44
4 <sup>c)</sup>	1	25	10% HOAc (v/v)	19	32
5 <sup>d)</sup>	1	65	10% HOAc (v/v)	6	3
6 <sup>b)</sup>	60	60	10% HOAc (v/v)	6	6
7 <sup>e)</sup>	-	25	10% HOAc (v/v)	7	7

a) 0.50 mmol (198 mg) **104**, 20 ml MeOH, 10 mol% Rh/C (5%); b) reaction carried out in a sealed autoclave; c) 40 ml MeOH; d) no catalyst used; e) no hydrogen used; f) estimated from <sup>1</sup>H-NMR of the crude reaction mixture without internal standard.

The experiments described in table **9** were either performed in regular *Schlenk* flasks with a balloon of hydrogen gas (for ambient pressure experiments; entries 1, 3-5) or in a sealed

autoclave for reactions under pressure (entries 2 and 6). Monitoring of the reaction was severely hampered by the fact that TLC analysis was not sufficient to clearly indicate product formation (nearly identical  $R_f$  and staining behavior of starting material **104** and products **203** and **204**). Therefore,  $^1\text{H-NMR}$  analysis had to be carried out to follow the reaction progress. Without the addition of an additive, there was almost no conversion detectable, even when conditions were forced to 60 °C and 60 bar (entries 1 and 2). Looking at the reaction times, it is noticeable that these processes were extremely slow and the conversion of starting material reached some kind of plateau after a certain time and then stopped completely. Best results were obtained when using 10% (v/v) acetic acid as an additive at ambient temperature and pressure, giving rise to 44% of conversion after 19 days (entry 3). Lower concentrations led to reduced reaction rate (32%, entry 4), whereas higher concentrations were not accomplishable due to the poor solubility of **104**. It could be shown by NMR and MS that methanol adducts **203** and **204** were formed in these transformations, but due to the low conversion and nearly identical  $R_f$  values of starting material **104** and the products **203** and **204**, it was practically impossible to completely purify and characterize the products. In none of the cases unsaturated elimination product **198** was observed. In order to check whether Rh/C is crucial for product formation, the attempt was made to convert **104** by simply refluxing it in methanol/acetic acid without catalyst addition (entry 5). However, only very little conversion was obtained after six days, indicating that rhodium indeed plays a role as catalyst. As described above, reaction rate seemed to be a limiting factor. Hence, we applied additional pressure and heat to the reaction conditions of entry 3 in order to accelerate the process. However, after six days of reaction at 60 °C and 60 bars of pressure only 6% conversion were determined (entry 6). When using Rh/C in MeOH/HOAc at room temperature without hydrogen gas, 7% conversion were observed after seven days (entry 7). If entries 5 and 7 are taken into account, it seems obvious that the investigated transformation is rather an acid-catalyzed process than a hydrogenation of the cyclopropane bond. Therefore, we turned our focus from hydrogenation approaches to acid-promoted transformations of bis-cyclopropane **104**.

### 3.4 Acid-promoted transformations of DA-cyclopropane **104**

As demonstrated earlier in chapter **B 3.3**, hydrogenolysis of the *push-pull* cyclopropane bonds in **104** is not an efficient process as cyclopropane cleavage rather proceeds via an acid-catalyzed ring opening mechanism. Hence, we investigated the effects of different *Brønstedt* and *Lewis* acids on their cyclopropane opening propensities, as well as suitable trapping reagents for the proposed iminium species **202**. Table **10** summarizes the attempts for such kind of transformations. From the previous experiments (entry 5 in table **9**), it is clear that refluxing methanol/acetic acid is not sufficient to induce cyclopropane ring opening. This leads to the conclusion that a suitable catalyst, capable of cyclopropane ring opening, needs to be employed. Indeed, scandium(III)-trifluoromethanesulfonate (scandium triflate; Sc(OTf)<sub>3</sub>) was shown to be highly efficient in opening both DA-cyclopropane rings in **104** (entries 1-3, see also ref. [60]). After only 5 min of microwave irradiation (heating at 85 °C), full conversion of starting material was observed. Unfortunately, only rearomatization and deprotection products could be isolated in this case (scheme **47**). The same was observed when bis-cyclopropane **104** was refluxed in methanol and activation with *para*-toluenesulfonic acid (*p*-TSA; entry 5). The ratio of the formed aromatic products **208** strongly depended on the reaction times. Under the acidic conditions (and elevated temperatures) an initial deprotection of the Boc group is likely before the ring opening takes place. However, the deprotection may also happen at a later stage. Yet in 1998, *Wenkert* and *Khatuya* reported on acid-mediated ring opening, and subsequent aromatization of doubly cyclopropanated furans **205** to form furan-3,4-diacetates of type **207**.<sup>[103]</sup> The authors proposed intermediates like **206**, which were claimed to be prone toward elimination (scheme **46**).

**Scheme 46.** Synthesis of furan-3,4-diacetates **207** from acid-mediated cyclopropane opening of **205** and subsequent elimination of HX from **206** by *Wenkert* and *Khatuya*.<sup>[103]</sup>

The fact that mixtures of several different ester functionalities (*t*Bu/Me and Me/Me) were isolated (**208**) leads to the assumption that the transesterification process takes place after the

formation of the pyrrole skeleton. Other *Lewis* acids ( $\text{LiClO}_4$ ,  $\text{FeCl}_3$ ,  $\text{AlCl}_3$ ) did also not yield products other than **208** (entries 6-8). In order to circumvent elimination, and thus rearomatization, the solvent was switched from methanol to less nucleophilic THF (entries 9-17) and the addition of triethylsilane was intended to provide hydride as a suitable nucleophile, which would not undergo elimination once added (see also scheme **47** for a plausible mechanism). However, this approach, though nice on paper, turned out to yield only decomposition products or unreacted starting material.

**Table 10.** Attempts for the acid-catalyzed cyclopropane opening of **104** (mw = microwave).

21 <sup>f)</sup>	THF	Sc(OTf) <sub>3</sub>	85-125 (mw)	Bn-NH <sub>2</sub>	2 h	< 5	<b>208</b>
------------------	-----	----------------------	----------------	--------------------	-----	-----	------------

a) 0.05 mmol (20 mg) **104**, 40 mol% acid, 1 ml solvent; b) 0.50 mmol (198 mg) **104**, 40 ml solvent; c) 100  $\mu$ l of water were added; d) 1.1 equiv *p*-TSA used; e) 5 equiv TFA were used; f) catalyst inhibition by amine; g) product inseparable from starting material (**208**: R = *t*Bu, R' = Bn); h) estimated from TLC.

Formation of aromatic compounds **208** in such reactions indicates that there seems to be an intermediary ring-opened methanol adduct of type **203/204** present (chapter **B 3.3**), which undergoes subsequent elimination of methanol (and Boc deprotection) to yield ring-opened pyrrole derivatives. A plausible mechanism for this type of transformation is shown in scheme **47**.

**Scheme 47.** Plausible mechanism for the acid-catalyzed ring opening and subsequent transformations of proposed intermediate **209**. When methanol acts as the nucleophile (*red*) elimination, and simultaneous pyrrole formation is encouraged (*upper row*). On the other hand, when hydride is used as the nucleophile, no elimination can take place, allowing for maintenance of the stereocenter(s) (LA = Lewis acid, *blue*).

After Lewis acid activation of the ester moiety a *push-pull* ring opening of the DA-substituted cyclopropane **209** takes place and the intermediary iminium ion **210** is trapped by a molecule of methanol. Intermediate **211** (or **212**) is prone to undergo elimination of methanol again to finally form pyrrole derivatives of type **208** under the applied conditions (scheme **47**, *upper row*). Ideally, one would envision using a nucleophile that is not able to undergo elimination. Thus, hydride may attack the iminium ion **210** to form products of type **213** (or **214**), which cannot undergo elimination and still maintain their stereoinformation (scheme **47**, *lower row*). Unfortunately, results from table **10** suggest that neither of the applied conditions were feasible for sufficient transformation of bis-cyclopropane **104** into the desired products **174** without the occurrence of aromatization. Thus, no further efforts were carried out in this direction.

## 4 Investigations of peptide foldamers at high pressure

### 4.1 High pressure as an alternative activation mode in organocatalysis

A general, until now only partly solved problem in organocatalysis is the slow reactivity of many of the catalysts compared to classic metal catalysis, leading to low turnover frequencies and to an instantaneous need for higher catalyst loadings.[211-215] In order to overcome energy barriers for organic transformations, several different modes of activation are feasible, e.g. an increase in temperature, the application of *Lewis* acids, microwave irradiation or ultrasonic sounds.[216, 217] Pressure is an alternative that was somehow ignored by a great part of the scientific community so far (due to plausible reasons, see discussion later); although it bears significant advantages compared to standard activation modes. It is a mild and non-destructive method that allows for activating a broad variety of organic transformations even at low temperatures, giving distinct benefits for selectivity issues. Reactions prone for activation by pressure include aldol, *Michael*, *Mannich* and *Baylis-Hillman* reactions, as well as cycloaddition reactions and cross couplings. In principle, every reaction with a negative *volume of activation* ( $\Delta V^\ddagger$ ), which is defined as the difference of the *volume of the transition state* and the *volume of the reactants*, can be accelerated by the influence of pressure.[218-221] Although literature precedents for pressure promoted reactions are rather limited, some remarkable transformations have been accomplished so far.[222-227] It can be assumed that the normally rather sophisticated experimental setup for such reactions excluded more intense application of high pressure in catalysis. However, people are creative and thus developed simple strategies for the generation of high pressures. For instance, *Hayashi* and co-workers reported a very elegant method by freezing water inside a sealed autoclave with a household refrigerator/freezer to  $-20\text{ }^\circ\text{C}$ , which enabled them to generate pressures of up to 2000 bar.[228-231] Some very recent examples include high pressure catalysis combined with photochemistry,[232, 233] as well as the highly enantioselective construction of chiral quaternary stereocenters applying pressures up to 10 kbar, which leads to products that are not accessible under ambient conditions.[234, 235]

## 4.2 Peptide based organocatalysts

Short peptides have been shown to be remarkably efficient catalysts for organocatalytic transformations and have been applied in a broad scope of transformations. The field of peptide based organocatalysis has been pioneered by *Miller et al.*[236, 237] and extensively augmented by the group of *Wennemers*.[238, 239] Figure 18 depicts two prominent examples from the referred groups (**215** and **216**).

**Figure 18.** Examples of peptidic organocatalysts from *Miller et al.* (**215**) and *Wennemers et al.* (**216**), along with tripeptide foldamers **217a** and **217b** from the *Reiser* group (▲ designates (+)-*cis*- $\beta$ -ACC ((+)-**33**), and ▼ designates (-)-*cis*- $\beta$ -ACC ((-)-**33**)).

Various studies revealed that regular peptides are often too flexible to act efficiently, thus modification by e.g. N-methylation or introduction of conformationally constrained building blocks proved to be vital for the construction of efficient catalyst systems. Tripeptide foldamers like **217a** and **217b**, containing a  $\beta$ -ACC (▲ or ▼) building block in the central position were shown to be efficient catalysts for organocatalytic transformations, including aldol, *Mannich*, and *Michael* reactions.[58, 240] Making use of the rigidity of the central cyclopropane moiety the two functional groups responsible for catalysis, i.e. the secondary amine and the carboxylic acid function can be positioned in close proximity. This feature allows **217a** (containing ▲) to act as a superior catalyst compared to its isomer **217b** (containing ▼). In the following part a plausible explanation for the discrepancy in catalytic activity between **217a** and its isomer **217b**, based on high-pressure (HP) structural studies (including HP-NMR), compared with catalytic results at high- and ambient-pressure conditions is proposed. The synthesis of the two tripeptide foldamers is described in the following section.

### 4.3 Synthesis of the tripeptide foldamers 217a and 217b

The synthesis of tripeptide foldamers **217a** and **217b** commences with the preparation of the central cyclopropane amino acid *cis*- $\beta$ -ACC ( $\blacktriangle/\blacktriangledown$ ; ( $\pm$ )-**220**) following a method of *Reiser et al.*[50] In this case **33** is prepared in a racemic fashion, as the enantiomers can be separated at a later stage (as diastereomeric dipeptides **221**), hence giving rise to both isomers at once. After *N*-Boc protection of pyrrole **50** using a slightly modified procedure of *Grehn and Ragnarsson*,[241] a racemic cyclopropanation reaction of *N*-Boc-pyrrole **101** was carried out using methyl diazoacetate to form cyclopropane ( $\pm$ )-**18** (scheme 48). The remaining double bond was subsequently cleaved via ozonolysis and treatment with dimethylsulfide (DMS) to form aldehyde **218**. In the next step, the aldehyde function was oxidized to the carboxylic acid following a procedure of *Dalcanale and Montanari*. [242, 243] After a deformylation step mediated by the organic base *N,N*-diethylaminoethylamine (DEAEA), benzyl protection of the free acid concludes the synthesis of racemic ( $\pm$ )-**220**.

**Scheme 48.** Synthesis of ( $\pm$ )-**220** from pyrrole **50** following the procedure of *Reiser et al.*[50]

Single crystals of the racemic mixture of **33**, suitable for X-ray analysis could be grown, allowing for a structural proof of the *cis*-relationship of the amine and the carboxylic acid moieties in **33** (figure 19).

**Figure 19.** Single crystal X-ray structure of Boc-▼-OH (**33**), clearly showing the *cis*-relationship of the amine and the carboxylic acid function. This structural feature is crucial for further approaches into catalysis, as it allows for spatial proximity of the functional groups responsible for catalytic activity.

After successful synthesis of racemic **220**, the preparation of the tripeptide catalysts followed another report of *Reiser et al.*,<sup>[58]</sup> which is presented in scheme **49**. As donor-acceptor substituted cyclopropanes are known to undergo rapid ring opening reactions once the N-terminus is deprotected,  $\beta$ -ACC derivatives proved to be tricky substrates for peptide coupling approaches.<sup>[48, 244, 245]</sup> Nevertheless, it is possible to synthesize dipeptides of type **221** by the deprotection of the *N*-Boc group with a solution of HCl in dry ethylacetate.<sup>[54]</sup> The resulting ammonium derivatives are stable enough to directly convert them into the corresponding dipeptides via solution phase peptide coupling with *N*-ethyl-*N'*-(3-dimethylaminopropyl)carbodiimide hydrochloride (EDC) and *N*-Boc-*L*-proline. For the separation of the two diastereomeric dipeptides, it is necessary to deprotect the Boc group first, as chromatographic separation proved to be much more convenient at this stage. Thus, the two diastereomerically pure dipeptides could be obtained in 43% (**221a**) and 33% (**221b**) yield from racemic ( $\pm$ )-**220**, respectively. The next steps are then performed in parallel for both isomeric compounds. After Boc protection and hydrogenolytic cleavage of the benzyl groups, the dipeptides are coupled with a second molecule of *L*-proline to form orthogonally protected tripeptides **222a** and **222b**. Final deprotection steps were carried out using HCl/EtOAc with subsequent basic work-up, followed by hydrogenation in order to cleave the benzyl esters. In this way tripeptide H-Pro-▲-Pro-OH (**217a**) was prepared in 5.0% yield over 13 steps (from *N*-Boc-pyrrole), and its isomer H-Pro-▼-Pro-OH (**217b**) in 4.1% (scheme **49**).

**Scheme 49.** Synthesis of tripeptide organocatalysts **217a** and **217b** from **(±)-220**, following the procedure of *Reiser et al.* (solely *L*-proline was used for peptide coupling).[58]

#### 4.4 Structural investigations of the tripeptide foldamers **217a** and **217b**

In order to gain insight into the possible conformations of the two peptidic organocatalysts **217a** and **217b**, we performed detailed structural investigations, including NMR studies combined with molecular modeling approaches. The findings from our structural studies were then compared to the results obtained from catalysis experiments (chapter **B 4.5**). From former studies it is known that H-Pro-▲-Pro-OH (**217a**) is a superior catalyst compared to its isomer H-Pro-▼-Pro-OH (**217b**).<sup>[58, 59]</sup> With the experiments discussed in the following part we aimed to create a reasonable explanation for the catalytic discrepancy of the two title compounds, and to propose a plausible way of catalytic action for the active species.

When having a look at the proton NMR spectra of the two isomeric compounds **217a** and **217b**, one immediately recognizes a significant difference.<sup>[58]</sup> While the spectrum looks tidy for **217b**, with nice sharp and separated signals, there is a vast overlap of mostly broadened signals visible for **217a**. Furthermore, one can see multiple distinct sets of signals, which might be assigned to minor populated state conformations. These first insights led to the postulation that **217a** is conformationally highly flexible, while its isomer **217b** is rather fixed to one major conformation, which may be due to an internal hydrogen bond. In order to test our hypothesis, <sup>1</sup>H-NMR spectra of both compounds were recorded at varying pressures (30, 1000, 2000 bar), and the relative shifts of the characteristic amide proton (*red* NH in figure **20**) were compared. In general, amide protons of peptides and proteins tend to shift much higher upon an external stimulus (e.g. temperature, solvent titration), when they are not hydrogen bonded. Thus, a minor shift of the amide signal may give hints for H-bonding of the amide proton in question.<sup>[246]</sup> Figure **20** presents the results of the conducted experiments.

**Figure 20.**  $^1\text{H-NMR}$  spectral region of the signal of the amide proton (red) of **217a** (A) and **217b** (B) at varying pressures (30, 1000, 2000 bar). The relatively low shift of the signal of **217b** and the occurrence of peak fine structure are clear hints for strong intramolecular H-bonding (800 MHz,  $\text{CD}_3\text{OH}$ , 0.18 M, 298 K).

It is clearly visible from the stacked  $^1\text{H-NMR}$  spectra depicted in figure 20 that the amide signal shifts to a much larger extent for **217a** ( $\Delta\delta_{\text{NH}} = 0.105$  ppm, A) compared to **217b** ( $\Delta\delta_{\text{NH}} = 0.058$  ppm, B). Furthermore, it has to be noticed that the signals are much sharper and start to split into the characteristic doublet of backbone amide protons in peptides (B). All together, these observations confirm our hypothesis and lead us to the conclusion that a strong intramolecular hydrogen bond fixes the conformation of **217b**. Structural calculations on the C-terminal benzyl ester of **217b** also revealed potential H-bond formation.[59, 247] As this tripeptide is the one showing poor catalytic performance, it is suggested that the internal H-bond separates the two functional groups responsible for catalytic activity, thus leading to an inactive catalyst. On the other hand, H-Pro-▲-Pro-OH (**217a**) is highly flexible, allowing for positioning of the functional groups into the desired conformation. It was already shown by *Reiser et al.* that **217a** exists in predominantly two major conformations.[58] At ambient temperature **217a** was shown to exist in a 1:3 *cis/trans* ratio in methanol- $d_3$ , whereas the minor *cis*-amide conformer was proposed to be the catalytically active species. X-ray analysis of peptide **217a** was not possible due to the high intrinsic flexibility (tripeptide **217b** could be crystallized but the obtained crystals were unfortunately not measurable). Moreover, this

would only lead to solid state insights, whereas the solution structure is much more important in this case. Therefore, we attempted to generate molecular models of the tripeptides, which would allow a more detailed perception into the structural preferences of the latter. The molecular modeling software package *Spartan 06* was used for the conformational sampling and energy calculations. Figure 21 presents low energy structures of tripeptides **217a** and **217b** obtained from a conformational search using six rotatable backbone bonds each without distance restraints. The resulting structures (324) were then minimized in energy and sorted afterwards. Due to severe overlap of the NMR signals, precise integration of all nuclear *Overhauser* effect (NOE) cross peaks could not be achieved, however, distinct NOEs were found for all of the proposed conformations and were taken into account in the process of sorting the conformers. Regarding this aspect, it has to be noted that the conformations of tripeptides **217a** and **217b** presented in figure 21 are rather ideal model structures than exact reflections of what actually happens in solution.

**Figure 21.** Low energy models of tripeptides **217b** (left) and **217a** (center, right) generated by *Spartan 06*. It is assumed that **217b** is stabilized by a strong intramolecular H-bond (green), which separates the two crucial functions (NH<sup>1</sup> and HO<sup>19</sup>) from each other (left). In contrast, **217a** exists in predominantly two conformations (*cis* and *trans*), from which only the minor conformation with a *cis*-amide bond would be the catalytically active species (center), while the *trans*-conformation has some kind of *resting state character* (in the chemical structures the groups responsible for catalytic activity are highlighted in red; blue arrows give distances between NH<sup>7</sup>-OC<sup>13</sup>, and NH<sup>1</sup>-HO<sup>19</sup> in Å; H-bonds with corresponding distances are indicated in green).

The low energy structure of tripeptide **217b** shows a potential hydrogen bond ( $d = 1.994 \text{ \AA}$ ) between  $\text{NH}^7$  and  $\text{OC}^{13}$ , which has also been predicted by the abovementioned experiments. In such a conformation the two functional groups responsible for efficient catalysis are spatially separated ( $7.094 \text{ \AA}$ ); a structural feature which would disallow bifunctional organocatalysis, and therefore explain the poor catalytic performance of **217b** (*left part* of figure 21). In contrast to **217b**, **217a** is suggested to be rather flexible, allowing for rapid changes of conformation. The two major conformations are proposed to be *cis/trans*-isomers of the C-terminal amide bond ( $\text{OC}^{13}\text{-N}$ ).<sup>10</sup>[248] In both, the *cis*-amide conformation (*center*) and the *trans*-amide conformation (*right*) the distances between  $\text{NH}^7$  and  $\text{OC}^{13}$  are rather large ( $3.422 \text{ \AA}$  and  $3.464 \text{ \AA}$ , respectively) and out of plane, thus avoiding a restraining H-bond similar to **217b**. The minor populated *cis*-conformer (*center*) shows close spatial proximity of the catalytically active functional groups with two weak H-bonds arranging them in space ( $\text{NH}^7\text{-CO}^{18}$ :  $1.899 \text{ \AA}$ ,  $\text{HN}^1\text{-HO}^{19}$ :  $1.821 \text{ \AA}$ ). On the other hand, the *trans*-conformation of **217a** (*right*) represents a kind of *resting state* of the catalyst, but though allows for rapid interconversion of the conformers.

**Figure 22.**  $^1\text{H-NMR}$  spectral region of the amide signal of tripeptide **217a** at varying pressures (30-2000 bar). While the amide signal of the major conformer (*left*) only shows shifting and marginal line sharpening upon increasing pressure, the region of minor populated conformational states (*red frame*) reveals distinct changes (800 MHz,  $\text{CD}_3\text{OH}$ , 0.18 M, 298 K).

In order to investigate whether pressure can influence the conformational equilibrium of our catalyst, we investigated the  $^1\text{H-NMR}$  amide region of H-Pro- $\blacktriangle$ -Pro-OH (**217a**) under

<sup>10</sup> For the conformations of proline amide bonds see: ref. [248]

varying pressures (figure 22). While the amide NH signal for the major conformer (*trans*, left part of the spectra) only showed shifting and rather insignificant line sharpening upon increasing pressure, the region of the minor populated conformational states revealed distinct effects (*red frame*). Indeed it seems that some of the signals are completely vanishing at higher pressures. This suggests a substantial effect of pressure on the conformational preferences of such a small peptide, which is remarkable. In order to provide more experimental proof for the proposed mechanism of action, we conducted experiments using tripeptides **217a** and **217b** as catalysts for aldol reactions at ambient- and high-pressure conditions.

#### 4.5 Organocatalysis under high pressure

It is a well-known fact that pressure influences the dissociation of water.[249] As it is also known that water plays a vital role in a plethora of organocatalytic transformations, it seems plausible to apply high pressure for the acceleration of said reactions. Despite of the effect on reactivity, it should also be investigated whether pressure can have an influence on the conformational equilibrium of the peptides, and thus could affect selectivity. Hence, tripeptide catalyst H-Pro- $\blacktriangle$ -Pro-OH (**217a**) was tested in the model reaction between acetone **223** and *para*-nitrobenzaldehyde **224** under ambient- and high-pressure conditions (table 11).

**Table 11.** Organocatalyzed aldol reactions under ambient- and high-pressure conditions.

entry <sup>a)</sup>	catalyst [mol%]	time [h]	pressure [bar] <sup>d)</sup>	conversion <sup>e)</sup>	yield [%] <sup>f)</sup>	ee [%] <sup>g)</sup>
1	-	24	1	40	17	0
2	-	24	4600	14	9	0
3	10	24	1	84	68	69 ( <i>R</i> )
4	10	16	5200	100	81	65 ( <i>R</i> )

6 <sup>b)</sup>	20	24	1	n.d.	89	78 ( <i>R</i> )
7 <sup>b),c)</sup>	20	24	1	n.d.	77	6 ( <i>R</i> )

a) 0.20 mmol (30 mg) **224**, 2 ml acetone/water (10:1 (v/v)); b) taken from ref. [58]; c) H-Pro-▼-Pro-OH, acetone/water (5:1 (v/v)); d) deviations of pressure are due to the experimental setup; e) determined by TLC analysis/isolated starting material; f) isolated yield after column chromatography; g) determined by chiral HPLC (Chiralcel AS-H, *n*-heptane/*i*PrOH = 99:1, flow = 0.5 ml/min,  $\lambda_{\text{max}} = 254$  nm,  $r_t = 18.97$  min (*R*),  $r_t = 22.38$  min (*S*)).

In order to see the potential effects of pressure on selectivity, a benchmark reaction with a moderate degree of enantioselectivity was chosen on purpose. From entries 1 and 2 it can be concluded that uncatalyzed background reactions indeed occur, but to a significantly lower extent at 5 kbar. When comparing entries 3 and 5, it becomes obvious that a pressure of 5 kbar leads to a sixfold increase in reaction rate (reaction time reduced from 24 h to 4 h). However, no significant effects on enantioselectivity were observed. Comparison of entries 6 and 7 reveals that H-Pro-▼-Pro-OH (**217b**) is still an active catalyst (leading to 77% yield), but conveys extremely poor selectivity (entry 7). This result nicely fits our proposed model, where the secondary amine (NH<sup>1</sup>) is widely separated from the acid function (OH<sup>19</sup>), but still is able to catalyze the reaction. It is assumed that the chiral information is transferred by the H-bonding capability of OH<sup>19</sup> (orienting the transition state), thus explaining the low enantioselectivity value for **217b** (6% *ee*). Although it was stated before that rigidity plays a crucial role in peptide catalyst activity, this example clearly demonstrates that a certain degree of conformational freedom can be essential for efficient catalytic performance.

#### 4.6 Structural investigations of longer $\alpha,\beta$ -peptide foldamers under high pressure

High pressure is a valuable tool in protein biochemistry as it enables the investigation of folding/unfolding mechanisms of proteins, which are of major concern with regard to diseases like *Alzheimer's* disease, *Parkinson's* disease or amyotrophic lateral sclerosis (ALS).[250] In most cases it is a non-invasive method that allows for tracking of folding intermediates, thus giving insight into conformational preferences of proteins and poly-peptides.[251, 252] In the following, we attempted structural studies of peptide foldamers with HP-NMR and HP-FTIR spectroscopy in order to explore the feasibility of such methods for systems much smaller than proteins.

**Figure 23.** Three-letter coded sequence and chemical structure of 13-residue  $\alpha/\beta$ -peptide foldamer **226**, including H-bonds (Cpe = cis-pentacin; digits on arrows indicate the number of atoms forming the H-bonded rings; *top*). NMR solution structures of **226** in methanol (*left*) and water (*right*). Foldamer **226** adopts a regular 9/12/9/10 helix in methanol solution. In contrast the helix is distorted to some extent in aqueous media, possibly due to hydrophobic interactions and  $\pi$ -stacking between the unsaturated rings (Cpe-2, Cpe-6, Cpe-10) on one face of the helix (*blue*), and formation of a salt-bridge between Lys-8 and Glu-12 on the opposite side (*orange*).

Mixed  $\alpha/\beta$ -peptide foldamers[253, 254] like **226** were designed using the so-called *stereochemical patterning approach* of Martinek and Fülöp *et al.*[255] and were shown to exhibit stable helical structures, even in aqueous media (figure **23**).[256, 257] In order to test

the power of HP-methods for structural studies of relatively short peptidic foldamers, we investigated the behavior of foldamer **226** as a model compound with HP-NMR (up to 2 kbar) and HP-FTIR (up to 6.5 kbar). The results of our experiments are summarized in the following section.

#### 4.6.1 High-pressure NMR experiments of foldamer **226**

NMR spectra of 13-residue peptide foldamer **226** were recorded in aqueous buffer at pressures ranging from ambient pressure (30 bar) to 2040 bar. The chemical shifts of the backbone amide signals – which are generally the most meaningful part of peptide or protein NMR spectra in terms of structural studies, as they reflect the backbone conformation – were analyzed (figure 24).

**Figure 24.** *Left:*  $^1\text{H}$ -NMR spectral region of the amide signals of foldamer **226** at varying pressures (30-2040 bar). Comparison of the signals for Ala-13 (*left red frame*) and Cpe-3 (*right red frame*) reveals non-uniform shifts of the amide signals, which indicates conformational changes of the helical backbone of the peptide foldamer. *Right:* Overlay of excerpts from NOESY spectra of **226** at 30 bar (blue) and 1830 bar (red). Arrows indicate pressure induced cross-peak shifts. 1D projection represents the  $^1\text{H}$ -NMR spectra of **226** at 30 bar according to the *blue* crosspeaks. (800 MHz, 20 mM aqueous phosphate buffer pH 7.4, 4 mM, 300 K, 800 ms mixing time).[258]

Obviously, the general trend upon increasing pressure is a low-field shift of most of the amide signals of **226**. However, some of the backbone amide proton signals do not move to a significant extent ( $\Delta\delta_{\text{NH}} = 0.007$  ppm for Cpe-3), while others shift quite intensely ( $\Delta\delta_{\text{NH}} = 0.060$  ppm for Ala-13). This feature is clear evidence that structural changes in the backbone conformation of the helical peptide occur, rather than solely compression of the helix, which would result in a constant shifting of all amide signals in question. Furthermore, the amide protons of the minor shifting signals show almost no changes of the  $J$ -coupling constants upon increasing pressure (Cpe-3:  $^3J_{\text{HH}}$  (30 bar) = 8.49 Hz,  $^3J_{\text{HH}}$  (2040 bar) = 8.41 Hz; Cpe-11:

$^3J_{\text{HH}}$  (30 bar) = 8.11 Hz,  $^3J_{\text{HH}}$  (2040 bar) = 8.24 Hz). Based on the low chemical shift differences and almost constant  $J$ -coupling values of such signals one can assume that these residues are rather buried in the interior of the helical structure and keep their strong hydrogen bonding character. On the other hand, terminal residues that are not incorporated within a strong hydrogen bonding network (e.g. Ala-13) tend to be more flexible.

#### 4.6.2 High-pressure FTIR experiments of foldamer 226

Infrared (IR) spectroscopy is a well-established technique for studying protein conformations.[259-262] In order to get a deeper insight into the conformational behavior of our model peptide **226**, we conducted HP-FTIR measurements, as it is known that protein secondary structures can be reliably assigned by using such methods.[263] Figure 25 depicts the amide-I band of the FTIR spectra (1600-1700  $\text{cm}^{-1}$ ) – which is mostly associated with the carbonyl stretching vibration – of foldamer **226** in  $\text{D}_2\text{O}$  under varying external perturbations (e.g. temperature and pressure). An approach for the cautious interpretation of the obtained data is described in the following.

**Figure 25.** Results from the pressure (**A** and **B**) and temperature (**C** and **D**) dependent FTIR measurements of foldamer **226** in  $D_2O$  at 298 K. Structural changes are reversible in regard of pressure (**B**) and temperature (**D**). FTIR spectra of **226** in  $D_2O$  and MeOH (**E**), and pressure dependency of secondary structure motifs (**F**; *black* = turn-like structures, *red* = helical structures, *green* = unordered structures, *blue* = usually associated with  $\beta$ -sheets, but in the present case may be assigned to short extended chains connecting the helical segments).

The FTIR amide-I band of **226** at ambient pressure shows a narrow band at around  $1672\text{ cm}^{-1}$ , usually associated with turn-like secondary structures (figure **25 A**). The broad band centered at around  $1640\text{ cm}^{-1}$  is an overlapping component between unordered motifs (at  $1638\text{--}45\text{ cm}^{-1}$ ) and  $\alpha$ -helical structures ( $1650\text{--}55\text{ cm}^{-1}$ ). Since the H-bonding pattern in the foldamer is different from that of a traditional  $\alpha$ -helix, differences in the wavenumbers are expected. For example, foldamer **226** likely forms 9/12/9/10 membered rings (compared with a 13 membered ring in an  $\alpha$ -helix), thus the helical structure formed by **226** is probably tighter and so the wavenumber is expected to be lower (similar to a  $3_{10}$ -helix which exhibits an IR band around  $1641\pm 3\text{ cm}^{-1}$ ).<sup>[262]</sup> Upon pressurization, the broadening of the amide-I band suggests a loss of well-defined structural motifs, and shifting of the peak associated with turns to higher wavenumber suggests weakened H-bonding (figure **25 A**). The peak-position dependent quantitative fits of the amide-I band with pressure (figure **25 F**) reveals a reduction in the contribution of the band at 1650 and  $1672\text{ cm}^{-1}$  (most likely: the loss of helical folds and turns), and a concomitant increase of the unordered structures ( $1636\text{--}1640\text{ cm}^{-1}$ ). Figure **25 B** shows that the changes prompted by pressure are reversible. The temperature-dependent measurements reveal a similar trend for the turn-like structures, but the changes in the helical/unordered region show an opposite behavior (figure **25 C**). Temperature induces a narrowing of the amide band at the low wavenumber side and a minor shift in the peak position. This could again arise due to a different H-bonding pattern at higher temperatures (also indicative of changes in the conformational equilibrium), but the changes are reversible (figure **25 D**). Figure **25 E** shows the amide-I band in methanol is blue shifted compared with the aqueous solution (probably mainly owing to the different solvent composition). Due to

less effective H-donor abilities of methanol, a blue-shift by about  $10\text{ cm}^{-1}$  in helical peptides has been reported.[264] In the present case, turn-like and helical structures exhibit shifts by 6 and  $9\text{ cm}^{-1}$ , respectively. In addition, a change of solvent from methanol to water causes a hydrophobic-collapse leading to partial loss of helical geometry, also evident by the shape of the amide-I band. These results suggest that the broad band centered at  $1640\text{ cm}^{-1}$  most likely reflects the conformational equilibrium between purely helical and partially collapsed conformations, which is changed reversibly by pressure, temperature and solvent.

In conclusion, both, NMR and IR measurements of  $\alpha/\beta$ -peptide foldamer **226** indicate a partial unfolding of the helical conformation upon increasing pressure, which was shown to be of a reversible nature.

#### 4.6.3 Temperature-dependent CD spectroscopy of foldamer **226**

Circular dichroism (CD) spectroscopy has been shown to be an invaluable methodology for the analysis of secondary structures of proteins and peptides.[265] Although the characteristic CD signals for regular  $\alpha$ -peptides do vary significantly from those of  $\beta$ -peptides or mixed  $\alpha/\beta$ -peptide foldamers, CD has nevertheless been shown to be appropriate for conformational studies of the latter.[266, 267] CD spectroscopy under high-pressure conditions has been realized,[268] but unfortunately, due to limitations in the experimental setup such measurements could not be conducted in the present work. Nevertheless, variable temperature (VT) CD spectroscopy has the potential to reveal insights into the thermal stability of secondary structures and can also indicate changes in secondary structure upon the external stimulus. Furthermore, the obtained data from temperature-dependent CD can directly be compared to those from temperature-dependent FTIR spectroscopy (chapter **B 4.6.2**). The CD spectrum of  $\alpha/\beta$ -peptide foldamer **226** in water shows a strong positive *Cotton* effect at 206 nm (figure **26**), which was assigned to a right-handed helix (confirmed by NMR solution structure and theoretical calculations).[256] In order to investigate the structural behavior of foldamer **226** under thermal ‘stress’, CD spectra of **226** in water at varying temperatures were collected and analyzed (figure **26**).

**Figure 26.** *Left:* Temperature-dependent circular dichroism spectra of peptide foldamer **226** in water at temperatures ranging from 10 °C to 90 °C (arrow indicates the decrease of molar ellipticity of the maximum at 206 nm with increasing temperature). *Right:* Thermal unfolding behavior of **226** based on the temperature-induced variation of the maximum at 206 nm. (Data from ref. [256]. Copyright: Wiley-VCH Verlag GmbH & Co. KGaA. Reproduced with permission).

As expected, the characteristic maximum at 206 nm decreases upon increasing temperature from 10 °C to 90 °C (*left part* in figure 26). Plotting of the temperature-induced variation of the CD maximum at 206 nm against temperature reveals a linear behavior and gives insight into the thermal unfolding of foldamer **226**. In these experiments, a remarkably high helical stability of **226** with only 35% unfolding at 90 °C was discovered (*right part* of figure 26). In analogy to the abovementioned structural features of **226** revealed by HP-NMR, HP-IR and VT-IR, the thermal unfolding behavior of foldamer **226** was also shown to be reversible by CD spectroscopy.

## C Summary

Cyclopropanated heterocycles have been shown to be invaluable building blocks for the synthesis of a broad variety of natural products and other biologically relevant compounds. The first part of the present thesis describes the enantioselective cyclopropanation of furan and pyrrole derivatives, as well as their further transformations of the derived compounds. Furan-3-carboxylic acid methyl ester **91** was used as starting material for the total synthesis of (-)-Paeonilide **27**, however, only in 83% *ee*, as enantiopure material was not accessible at that time. In the course of this project an enantioselective cyclopropanation reaction of **91** was developed, which leads to cyclopropane **15** in > 99% *ee* and multi-gram quantity (scheme 50).

**Scheme 50.** Enantioselective cyclopropanation of furan-3-carboxylic acid methyl ester **91** on 100 mmol scale.

Key features for the success were the application of azabox ligand **8** as the chiral ligand and the modification of the ratio of catalyst to ligand from 1:1 to 1:2. On the other hand, cyclopropanation products of *N*-Boc-pyrrole **101**, which already have been applied for various synthetic endeavors, could not be accessed by enantioselective cyclopropanation so far. In the present work, a strategy for the enantioselective cyclopropanation of **101** with the use of *tert*-butyl diazoacetate as carbene source and again azabox ligand **8** was developed (scheme 51).

**Scheme 51.** Enantioselective cyclopropanation of *N*-Boc-pyrrole **101** on 150 mmol scale.

Cyclopropane **103** can be obtained in > 99% *ee* and multi-gram quantity, along with doubly cyclopropanated **104** (max. 41% *ee*). The application of *tert*-butyl diazoacetate and the ligand **8** turned out to be crucial for achieving high enantiomeric excess of the product. In the course of this project *tert*-butyl substituted azabox ligand **8** was identified to be superior to a great variety of other ligands for the asymmetric cyclopropanation of both **91** and **101**. Cyclopropane **103** was applied for a short and efficient synthesis of the biologically active GABA analogue (*S*)-(+)-homo- $\beta$ -proline **109** (scheme 52).

**Scheme 52.** Synthesis of (*S*)-(+)-homo- $\beta$ -proline **109** from cyclopropane **103**.

Starting from *N*-Boc-pyrrole **101**, (*S*)-(+)-**109** could be prepared in three steps and 37% yield. However, the occurrence of epimerization during the acid catalyzed cyclopropane ring opening step prohibited access to enantiomerically pure **109**.

In the second part of the present thesis the structural and conformational behavior of  $\alpha/\beta$ -peptide foldamers were investigated by the application of high-pressure NMR (up to 2 kbar) and FTIR (up to 6.5 kbar) spectroscopic methods. Short tripeptides **217a** and **217b** containing a central cyclopropane amino acid, were analyzed in terms of their catalytic performance related to the application of pressure (figure 27).

**Figure 27.** Chemical structures of tripeptide organocatalysts **217a** and **217b** for the intermolecular aldol reaction of acetone **223** and *para*-nitrobenzaldehyde **224**.

The fact that **217a** acts as a highly efficient organocatalyst for intermolecular aldol reactions, while its enantiomer **217b** gives poor results, led us to the investigation of this feature. A plausible model for explaining the discrepancy of catalytic performance of **217a** and **217b** was proposed. While **217b** shows clear indications for a strong internal hydrogen bond that separates the two catalytic functional groups, **217a** shows a significantly higher degree for flexibility that allows it for reaching an optimal conformation for catalysis. Experiments under high-pressure conditions revealed a sixfold increase in reaction rate upon a pressure jump from 1 bar to 5 kbar, but this was rather assigned to the general effect of pressure than to a change of the equilibrium of conformations of **217a**. In addition to short tripeptides **217a** and **217b**, the 13-residue  $\alpha/\beta$ -peptide foldamer **226** was examined under variable pressure and temperature. Conformational studies by NMR, FTIR and CD spectroscopy revealed a partial unfolding of the helical structure of **226** at elevated pressures and temperatures, which was shown to be reversible.

## D Zusammenfassung

Cyclopropanierte Heterocylen haben sich als unschätzbare Bausteine für die Synthese einer großen Vielfalt an Naturstoffen und anderen biologisch relevanten Molekülen bewährt. Der erste Teil der vorliegenden Arbeit behandelt die enantioselektive Cyclopropanierung von Furan- und Pyrrolderivaten, sowie die weitere Umsetzung der hierbei erhaltenen Verbindungen. Furan-3-carbonsäuremethylester **91** wurde als Grundlage für die Totalsynthese von (-)-Paeonilid **27** eingesetzt, jedoch nur in 83% *ee*, da enantiomerenreines **15** zum Zeitpunkt der Veröffentlichung noch nicht zugänglich war. Im Laufe dieser Arbeit wurde eine enantioselektive Cyclopropanierungsreaktion von **91** entwickelt, welche Cyclopropan **15** in > 99% *ee* und Multigrammmaßstab liefert (Schema 1).

**Schema 1.** Enantioselektive Cyclopropanierung von Furan-3-carbonsäuremethylester **91** im 100 mmol Maßstab.

Die Kernpunkte für den Erfolg waren der Einsatz von Azabox Ligand **8** als chiralen Liganden, sowie die Veränderung des Verhältnisses von Katalysator zu Ligand von 1:1 zu 1:2. Neben Furanen sind auch die Cyclopropanierungsprodukte von Pyrrolen von Interesse, jedoch konnte bisher keine Möglichkeit zur asymmetrischen Cyclopropanierung von *N*-Boc-Pyrrol **101** gefunden werden. In der vorliegenden Arbeit wurde eine Strategie zur enantioselektiven Cyclopropanierung von **101** unter der Verwendung von *tert*-Butyldiazoester als Carbenquelle und wiederum **8** als chiralem Liganden entwickelt (Schema 2).

**Schema 2.** Enantioselective Cyclopropanierung von *N*-Boc-Pyrrol **101** im 150 mmol Maßstab.

Cyclopropan **103** kann hierbei in  $> 99\%$  *ee* und Multigrammmaßstab, zusammen mit doppelt cyclopropaniertem **104** (max. 41% *ee*) erhalten werden. An dieser Stelle erwies sich die Kombination von *tert*-Butyldiazoester und Ligand **8** als essentiell, um hohe Enantiomerenüberschüsse des Produktes **103** zu erhalten. Im Laufe dieser Untersuchungen kristallisierte sich der *tert*-Butyl substituierte Azabox Ligand **8** als herausragend für die asymmetrische Cyclopropanierung von **91** und **101** heraus. Desweiteren wurde Cyclopropan **103** für eine kurze und effiziente Synthese des biologisch aktiven GABA Analogons (*S*)-(+)-homo- $\beta$ -Prolin **109** verwendet (Schema 3).

**Schema 3.** Synthese von (*S*)-(+)-homo- $\beta$ -Prolin **109** ausgehend von Cyclopropan **103**.

Das Zielmolekül (*S*)-(+)-**109** konnte in nur drei Stufen und 37% Ausbeute ausgehend von *N*-Boc-Pyrrol **101** erhalten werden. Nichtsdestotrotz verhinderte das Auftreten von Epimerisierung während der säurekatalysierten Cyclopropanöffnung die vollständig enantiomerenreine Darstellung von **109**.

Im zweiten Teil der vorliegenden Arbeit wurden die strukturellen und konformativen Eigenschaften von gemischten  $\alpha/\beta$ -Peptidfoldameren unter Anwendung von Hochdruck-NMR (bis zu 2 kbar) und Hochdruck-IR (bis zu 6.5 kbar) Spektroskopie untersucht. Kurze Tripeptide mit einem zentralen Cyclopropanbaustein **217a** und **217b** wurden hierbei bezüglich ihrer katalytischen Aktivität unter dem Einfluss von Druck untersucht (Abbildung 27).

**Abbildung 1.** Chemische Strukturformeln von Tripeptid-Organokatalysatoren **217a** und **217b** für die intermolekulare Aldolreaktion von Aceton **223** und *para*-Nitrobenzaldehyd **224**.

Die Tatsache, dass **217a** ein hocheffizienter Organokatalysator für intermolekulare Aldolreaktionen ist, während sein Enantiomer **217b** nur mäßigen Erfolg einbringt, wurde als Grundlage für die Untersuchungen dieser Arbeit genommen. Ein plausibles Modell für die Erklärung des unterschiedlichen katalytischen Verhaltens von **217a** und **217b** wurde hierin vorgestellt. Während **217b** klare Anzeichen für eine starke interne Wasserstoffbrücke zeigt, welche die beiden für die Katalyse notwendigen funktionellen Gruppen räumlich separiert, ist sein Isomer **217a** deutlich flexibler und kann dadurch leichter eine ideale Konformation für die Katalyse erreichen. Katalysen unter Hochdruckbedingungen zeigen einen sechsfachen Anstieg der Reaktionsgeschwindigkeit bei einem Druckanstieg von 1 bar nach 5 kbar, was jedoch eher auf den generellen Einfluss des Drucks, als eine Änderung des Konformationsgleichgewichts von **217a** zurückzuführen ist. Zusätzlich zu den kurzen Tripeptiden **217a** und **217b** wurde auch ein längeres  $\alpha/\beta$ -Peptidfoldamer (13 Aminosäurebausteine) unter druck- und temperaturabhängigen Bedingungen untersucht. Konformative Untersuchungen mittels NMR, FTIR und CD Spektroskopie zeigen eine partielle Entfaltung der helikalen Struktur von **226** bei hohen Drücken und Temperaturen, welche aber reversibel ist.

## E Experimental part

### 1 Instruments and general techniques

**<sup>1</sup>H-NMR** spectra were recorded on Bruker Avance 300 (300 MHz), Bruker Avance 400 (400 MHz) and Bruker Avance III 600 TCI Cryo (600 MHz). The chemical shifts are reported in  $\delta$  (ppm) relative to chloroform (CDCl<sub>3</sub>, 7.26 ppm), methanol-*d*<sub>3</sub> or methanol-*d*<sub>4</sub> (CD<sub>3</sub>OH, 3.34 ppm). The spectra were analyzed by first order, the coupling constants (*J*) are reported in Hertz (Hz). Characterization of the signals: s = singlet, bs = broad singlet, d = doublet, t = triplet, q = quartet, quin = quintet, m = multiplet, dd = double doublet, ddd = double double doublet, dt = double triplet, dquin = double quintet, po = pseudo octet. Integration is determined as the relative number of atoms.

**<sup>13</sup>C-NMR** spectra were recorded on Bruker Avance 300 (75.5 MHz) and Bruker Avance 400 (100.6 MHz). The chemical shifts are reported in  $\delta$  (ppm) relative to chloroform (CDCl<sub>3</sub>, 77.0 ppm) or methanol-*d*<sub>4</sub> (MeOD, 49.0 ppm). <sup>13</sup>C-NMR resonance assignment was aided by the use of HSQC, DEPT 135 and DEPT 90 techniques (DEPT = distortionless enhancement by polarization transfer) to determine the number of hydrogens attached to each carbon atom and is declared as: + = primary or tertiary (CH<sub>3</sub>, CH, positive DEPT signal), - = secondary (CH<sub>2</sub>, negative DEPT signal), Cq = quaternary (no DEPT signal) carbon atoms.

**High-pressure NMR** was performed on Bruker Avance 800 (800 MHz) in the group of Prof. H. R. Kalbitzer in the Institute of Biophysics and Physical Biochemistry at the University of Regensburg. A ceramic cell containing the sample solution was inserted into a titanium autoclave and external pressure was applied via a flexible polyethylene terephthalate (PET) membrane and water as compression fluid. Pressure was generated and maintained via a manually operated piston compressor. For a detailed description of the experimental setup see: [258]

**Infrared spectroscopy (IR)** in form of ATR-IR spectroscopy was carried out on a Biorad Excalibur FTS 3000 spectrometer, equipped with a Specac Golden Gate Diamond Single Reflection ATR-System. Pressure- and temperature dependent FTIR spectra were collected by

Prof. Roland Winter in the Faculty of Chemistry and Chemical Biology at the TU Dortmund. A diamond anvil cell served as the reaction vessel for the measurements. For a detailed description of the experimental setup see: [269]

**Mass spectrometry (MS)** was performed in the Central Analytic Department of the University of Regensburg on Finnigan MAT 95, ThermoQuest Finnigan TSQ 7000, Agilent Q-TOF 6540 UHD and Finnigan MAT SSQ 710 A.

**Elemental analysis** was measured on a Vario EL III or Mikro-Rapid CHN (Heraeus) (Microanalytic section of the University of Regensburg).

**Optical rotations** were determined in a Perkin Elmer 241 polarimeter at 589 nm wavelength (sodium-*d*-line) in a 1.0 dm measuring cell and the specified solvent.

**Lyophilization** was carried out with a Christ alpha 2-4 LD equipped with a vacuubrand RZ 6 rotary vane vacuum pump.

**X-ray** analysis of single crystals was performed in the X-ray crystallographic Department of the University of Regensburg on Agilent Technologies SuperNova, Agilent Technologies Gemini R Ultra or Stoe IPDS I.

**High performance liquid chromatography (HPLC).** Analytical HPLC was performed on a Varian 920-LC with DAD. Phenomenex Lux Cellulose-1 and 2, Chiralcel OD-H and AS served as chiral stationary phase, and mixtures of *n*-heptane and *i*PrOH were used for elution.

**Thin layer chromatography (TLC)** was performed on alumina plates coated with silica gel (Merck silica gel 60 F 254,  $d = 0.2$  mm). Visualization was accomplished by UV light ( $\lambda = 254$  nm or 366 nm), iodine, ninhydrin/acetic acid solution, vanillin/sulfuric acid solution, potassium permanganate solution, *Seebach's Magic Stain*, or *Dragendorff-Munier* reagent.

**Circular dichroism spectroscopy (CD)** was performed on a JASCO model J-710/720 at temperatures between 10 °C and 90 °C and wavelengths between 280 and 190 nm in water, by using the following parameters: 0.2 nm resolution, 1.0 nm band width, 100 mdeg sensitivity, 0.25 s response, 20 nm/min speed, 5 scans. The length of the cuvette was 1.0 mm. The CD spectrum of the sole solvent was recorded and subtracted from the raw data. The peptide concentration of the samples was 1 mM. The CD intensity is given as mean-residue molar ellipticity ( $\text{deg cm}^2 \text{dmol}^{-1}$ ).

**Molecular modeling.** Molecular mechanical simulations were carried out using the *Wavefunctions Spartan 06* programme. For the conformational searches and energy calculations, the *Tripos Sybyl* force field was used. Six rotatable backbone bonds of tripeptides **217a** and **217b** were used, leading to 324 conformations each that were subsequently minimized in energy for both conformers. The resulting low energy structures were then sorted and analyzed.

**Solvents and chemicals.** DCM, ethyl acetate and hexanes (petroleum ether, PE (60/40)) were distilled prior to use for column chromatography. Dry solvents were prepared according to standard procedures. Commercially available chemicals were used as received, without further purification. A saturated solution of HCl in ethylacetate was prepared by inserting gaseous HCl (predried with conc. H<sub>2</sub>SO<sub>4</sub>) into a cooled solution of dry ethylacetate. The concentration of the solution was determined by titration against NaOH (1 M) with bromothymol blue as indicator to be 4.2 M. The solution was stored under nitrogen atmosphere at -20 °C.

**High-pressure reactions** up to 5 kbar were performed using a self-made hydraulic high-pressure apparatus from Unipress (Warsaw) using melted polytetrafluoroethylene (PTFE) tubes as reaction vessels. A 1:1 (v/v) mixture of decahydronaphthalene (decalin, *cis/trans* mixture) and 2,2,4-trimethylpentane (*iso*-octane) was used as pressurizing medium.

## 2 Synthesis of compounds

Following compounds were synthesized according to literature known procedures and spectroscopic data matched well with those reported:

4-Methylbenzenesulfonyl azide (tosyl azide),[270] methyl-2-diazoacetate,[271] ethyl-2-diazoacetate,[272] (*S*)-2-amino-3,3-dimethylbutan-1-ol ((*S*)-*tert*-leucinol **70**),[88] (*S*)-2-amino-3-methylbutan-1-ol ((*S*)-valinol),[89] (*S*)-4-isopropyl-4,5-dihydrooxazol-2-amine,[62] (*S*)-4-isopropylloxazolidin-2-one,[63] (*S*)-2-ethoxy-4-isopropyl-4,5-dihydrooxazole **75**,[63] 2-iodoxybenzoic acid (IBX).[273]

Azabox ligands other than **8**, **9**, **60** and **74** were either on stock in the laboratory or were prepared in analogy to the described synthesis of **8** (main part chapter **B 1.1**, scheme **7**), following the improved methodology of ref. [63].

*tert*-Butyl-2-diazoacetate[274]

*n*-Pentane (900 ml) was cooled to 0 °C and *tert*-butyl acetoacetate (52.8 ml, 318 mmol, 1.0 equiv), tosyl azide (62.6 g, 318 mmol, 1.0 equiv), and TBAB (2.05 g, 6.46 mmol, 0.02 equiv) were added. The mixture was treated with a precooled solution of NaOH (36 g in 300 ml water, 0.9 mol, 2.8 equiv) over a period of 15 min. Afterwards, the cooling bath was removed and the solution was stirred for 15 h at room temperature. The reaction mixture was then filtered through a plug of Celite to remove precipitates and the filtrate was transferred into a separating funnel. After separation of the phases the aqueous layer was extracted with *n*-pentane (3 x). The combined organic layers were washed with water (2 x) and brine (1 x), dried over Na<sub>2</sub>SO<sub>4</sub> and finally concentrated under reduced pressure (15 °C water bath) to yield the title compound *tert*-butyl-2-diazoacetate (43.3 g, 308 mmol, 96%) as a yellow oil that was diluted with DCM to the required concentration.

<sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>): δ<sub>H</sub> (ppm) = 1.48 (s, 9 H), 4.61 (s, 1 H).

*tert*-Butyl-1*H*-pyrrole-1-carboxylate (**101**)[241]

*N*-Boc protected pyrrole **101** was synthesized following a slightly modified procedure of *Grehn et al.* Freshly distilled pyrrole **50** (68.0 g, 1.01 mol, 1.0 equiv) was dissolved in DCM (450 ml) and DMAP (9.9 g, 0.08 mol, 0.08 equiv) was added. Boc<sub>2</sub>O (246.3 g, 1.13 mol, 1.1 equiv) was added portionwise and the mixture was stirred at room temperature until gas evolution stopped (48 h). The reaction mixture was treated with DEAEA (38 ml, 0.27 mol, 0.3 equiv) and stirred for further 30 min. Afterwards, the reaction mixture was concentrated to half its volume, washed with KHSO<sub>4</sub> (1 M, 3 x), NaHCO<sub>3</sub> (sat., 1 x), and the organic layer was dried over Na<sub>2</sub>SO<sub>4</sub>. After evaporation of the solvent, the crude residue was distilled under reduced pressure to yield **101** (139.6 g, 0.83 mol, 82%) as a colorless liquid.

$R_f = 0.60$  (PE/EA = 5:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 1.60 (s, 9 H), 6.20-6.23 (m, 2 H), 7.22-7.25 (m, 2 H). – bp = 80 °C/8 hPa.

Methyl-furan-3-carboxylate (**15**)[45]

Furan-3-carboxylic acid **88** (10.0 g, 89.2 mmol, 1.0 equiv) was dissolved in MeOH (45 ml) and cooled to 0 °C. H<sub>2</sub>SO<sub>4</sub> (conc., 10 ml) was added dropwise and the solution was stirred overnight at room temperature. The mixture was treated with water and extracted with Et<sub>2</sub>O (3 x). The combined organic layers were washed with NaHCO<sub>3</sub> (sat., 1 x), dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated under reduced pressure. The crude residue was distilled under reduced pressure to yield **15** (7.8 g, 61.7 mmol, 69%) as a colorless liquid.

$R_f = 0.69$  (PE/EA = 3:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 3.84 (s, 3 H), 6.74 (dd, 1 H,  $J = 1.9$  Hz, 0.8 Hz), 7.41-7.43 (m, 1 H), 8.00-8.02 (m, 1 H). – bp = 55 °C/8 hPa.

(*S*)-4-(*tert*-Butyl)-4,5-dihydrooxazol-2-amine (**70**)[62]

NaCN (2.57 g, 52.42 mmol, 1.05 equiv) was added portionwise to solution of Br<sub>2</sub> (2.69 ml, 52.42 mmol, 1.05 equiv) in MeOH (40 ml) at 0 °C. To that solution a solution of **70** (5.85 g, 49.92 mmol, 1.0 equiv) in MeOH (80 ml) was added and the mixture was stirred at 0 °C for 1 h. Aqueous ammonia (25% (m/m), 25 ml) was added and the mixture was concentrated in vacuo. The resulting residue was treated with NaOH (20% (m/m), 50 ml) and extracted with EA (4 x, 60 ml). After drying over MgSO<sub>4</sub> and filtration, the solvent was evaporated under reduced pressure to give **71** (5.17 g, 36.39 mmol, 73%) as a white solid.

$R_f = 0.04$  (PE/EA = 2:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 0.87 (s, 9 H), 2.75 (bs, 2 H), 3.74 (dd, 1 H,  $J = 9.3$  Hz, 7.1 Hz), 4.07 (dd, 1 H,  $J = 8.3$  Hz, 7.1 Hz), 4.22 (dd, 1 H,  $J = 9.2$  Hz, 8.3 Hz).

(*S*)-4-(*tert*-Butyl)oxazolidin-2-one (**72**)[63]

Sodium metal (0.58 g, 25.60 mmol, 1.0 equiv) was dissolved in EtOH (37 ml), the solution was treated with aminoalcohol **70** (3.00 g, 25.60 mmol, 1.0 equiv) and diethylcarbonate (3.41 ml, 28.16 mmol, 1.1 equiv), and the mixture was refluxed for 20 h. The solution was then concentrated under reduced pressure, treated with DCM and NH<sub>4</sub>Cl (sat.), and extracted with DCM (2 x). After drying over MgSO<sub>4</sub> and filtration the solvent was evaporated under reduced pressure to give a white solid that was recrystallized from Et<sub>2</sub>O to yield **72** (3.00 g, 20.93 mmol, 82%) as a white solid.

$R_f = 0.15$  (PE/EA = 2:1) –  $^1\text{H-NMR}$  (300 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{H}}$  (ppm) = 0.91 (s, 9 H), 3.59 (ddd, 1 H,  $J = 8.9$  Hz, 5.8 Hz, 0.9 Hz), 4.20 (dd, 1 H,  $J = 9.0$  Hz, 5.8 Hz), 4.34-4.41 (m, 1 H), 5.71 (bs, 1 H).

(*S*)-4-(*tert*-Butyl)-2-ethoxy-4,5-dihydrooxazole (**73**)[63]

A solution of oxazolidinone **72** (1.73 g, 12.06 mmol, 1.0 equiv) in dry DCM (15 ml) was cooled to 0 °C and a solution of triethyloxonium tetrafluoroborate (2.75 g, 14.47 mmol, 1.2 equiv) in DCM (9 ml) was added dropwise. The reaction was allowed to warm to room temperature and was stirred for 44 h. The reaction mixture was then poured into an ice-cold solution of  $\text{Na}_2\text{CO}_3$  (50 ml) and extracted with DCM (3 x). After drying over  $\text{Na}_2\text{SO}_4$  and filtration the solvent was evaporated under reduced pressure to give **73** (1.94 g, 11.33 mmol, 94%) as a pale yellow oil that was used without further purification.

$R_f = 0.67$  (PE/EA = 2:1) –  $^1\text{H-NMR}$  (300 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{H}}$  (ppm) = 0.88 (s, 9 H), 1.35 (t, 3 H,  $J = 7.1$  Hz), 3.76 (dd, 1 H,  $J = 9.4$  Hz, 6.7 Hz), 4.18 (dd, 1 H,  $J = 8.5$  Hz, 6.7 Hz), 4.23-4.34 (m, 3 H).

(*S*)-Bis((*S*)-4-(*tert*-butyl)-4,5-dihydrooxazol-2-yl)amine (**8**)[63]

Ethoxyoxazoline **73** (1.94 g, 11.33 mmol, 1.2 equiv) was dissolved in dry toluene (20 ml) and amino oxazoline **71** (1.34 g, 9.44 mmol, 1.0 equiv) was added. After addition of *p*-TSA (163 mg, 0.94 mmol, 0.1 equiv) the reaction mixture was refluxed under nitrogen for 16 h. The crude mixture was concentrated under reduced pressure and purified via flash chromatography (silica, PE/EA = 1:9) to yield **8** (2.27 g, 8.50 mmol, 90%) as a colorless crystalline solid that can be recrystallized from acetone.

$R_f = 0.33$  (EA) –  $^1\text{H-NMR}$  (300 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{H}}$  (ppm) = 0.86 (s, 18 H), 3.77 (dd, 2 H,  $J = 9.4$  Hz, 6.7 Hz), 4.11 (dd, 2 H,  $J = 8.8$  Hz, 6.6 Hz), 4.21-4.31 (m, 2 H), 8.61 (bs, 1 H). –  $^{13}\text{C-NMR}$  (101 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{C}}$  (ppm) = 25.3 (+,  $\text{CH}_3$ ), 33.6 (Cq), 67.4 (-,  $\text{CH}_2$ ), 68.7 (+, CH), 165.9 (Cq).

(*S*)-4-(*tert*-Butyl)-*N*-((*S*)-4-(*tert*-butyl)-4,5-dihydrooxazol-2-yl)-*N*-methyl-4,5-dihydrooxazol-2-amine (**9**)[62]

Ligand **8** (300 mg, 1.12 mmol, 1.0 equiv) was dissolved in dry THF (10 ml) and cooled to  $-78$  °C. *n*BuLi (1.6 M solution in *n*-hexane; 769  $\mu\text{l}$ , 1.23 mmol, 1.1 equiv) was added slowly and the solution was stirred for 20 min at  $-78$  °C, before MeI (351  $\mu\text{l}$ , 5.61 mmol, 5.0 equiv) was added and the reaction was stirred in the defrosting cooling bath overnight (17 h). Volatiles were removed in vacuo and the residue was treated with DCM and  $\text{NaHCO}_3$  (sat.). After phase separation the aqueous layer was extracted with DCM (3 x) and the organic layer was dried over  $\text{MgSO}_4$ . Evaporation of the solvent yielded pure **9** (269 mg, 0.96 mmol, 85%) as a white solid.

$R_f = 0.18$  (PE/EA = 1:2) –  $^1\text{H-NMR}$  (300 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{H}}$  (ppm) = 0.88 (s, 18 H), 3.41 (s, 3 H), 3.79 (dd, 2 H,  $J = 9.5$  Hz, 6.7 Hz), 4.23 (dd, 2 H,  $J = 8.5$  Hz, 6.7 Hz), 4.34 (dd, 2 H,  $J = 9.4$  Hz, 8.6 Hz). –  $^{13}\text{C-NMR}$  (101 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{C}}$  (ppm) = 25.5 (+,  $\text{CH}_3$ ), 34.0 (Cq), 37.4 (+,  $\text{CH}_3$ ), 70.3 (-,  $\text{CH}_2$ ), 73.2 (+, CH), 157.8 (Cq).

(*S*)-*N*-Benzyl-4-(*tert*-butyl)-*N*-((*S*)-4-(*tert*-butyl)-4,5-dihydrooxazol-2-yl)-4,5-dihydrooxazol-2-amine (**74**)<sup>11</sup>

Ligand **8** (276 mg, 1.03 mmol, 1.0 equiv) was dissolved in dry THF (10 ml) and cooled to -78 °C. *n*BuLi (1.6 M solution in *n*-hexane; 644 µl, 1.03 mmol, 1.0 equiv) was added slowly and the solution was stirred for 20 min at -78 °C, before BnBr (122 µl, 1.03 mmol, 1.0 equiv) was added and the reaction was stirred in the defrosting cooling bath overnight (20 h). Volatiles were removed in vacuo and the residue was treated with DCM and NaHCO<sub>3</sub> (sat.). After phase separation the aqueous layer was extracted with DCM (3 x) and the organic layer was dried over MgSO<sub>4</sub>. Evaporation of the solvent yielded pure **74** (357 mg, 1.00 mmol, 97%) as a white solid.

<sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>): δ<sub>H</sub> (ppm) = 0.73 (s, 18 H), 3.74 (dd, 2 H, *J* = 9.5 Hz, 6.6 Hz), 4.15 (dd, 2 H, *J* = 8.5 Hz, 6.5 Hz), 4.24-4.29 (m, 2 H), 4.91 (d, 1 H, *J* = 15.0 Hz), 5.10 (d, 1 H, *J* = 15.0 Hz), 7.12-7.27 (m, 3 H), 7.35-7.40 (m, 2 H). – <sup>13</sup>C-NMR (101 MHz, CDCl<sub>3</sub>): δ<sub>C</sub> (ppm) = 25.4 (+, CH<sub>3</sub>), 34.0 (Cq), 53.2 (-, CH<sub>2</sub>), 70.1 (-, CH<sub>2</sub>), 73.4 (+, CH), 127.1 (+, CH), 128.1 (+, CH), 137.8 (Cq), 157.2 (Cq).

(*S*)-Bis((*S*)-4-*iso*-propyl-4,5-dihydrooxazol-2-yl)amine (**60**)

Ethoxyoxazoline **75** (297 mg, 1.89 mmol, 2.0 equiv) was dissolved in dry MeOH (5 mL) under a nitrogen atmosphere. A solution of gaseous NH<sub>3</sub> in MeOH (7 M, 0.14 ml, 0.95 mmol, 1.0 equiv) was added slowly and the reaction mixture was heated to 80 °C for 24 h. The reaction mixture was allowed to cool to ambient temperature and was then extracted with

<sup>11</sup> Ligand **74** was prepared in analogy to **9**, with benzyl bromide as alkylating agent. So far, different methods have been employed for the synthesis of **74** in literature.

DCM (3 x). The organic layers were dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and the solvent was evaporated under reduced pressure. The crude mixture was purified via flash chromatography (silica, EA) to yield azabox **60** (36 mg, 0.15 mmol, 16%) as a colorless crystalline solid.

$R_f = 0.35$  (EA) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 0.88 (d, 6 H,  $J = 6.8$  Hz), 0.96 (d, 6 H,  $J = 6.7$  Hz), 1.70 (po, 2 H,  $J = 6.7$  Hz), 3.75-3.85 (m, 2 H), 4.03 (dd, 2 H,  $J = 8.5$  Hz, 7.1 Hz), 4.32-4.51 (m, 2 H), 8.47 (bs, 1 H). – <sup>13</sup>C-NMR (75 MHz, CDCl<sub>3</sub>):  $\delta_C$  (ppm) = 18.1 (+, CH<sub>3</sub>), 18.7 (+, CH<sub>3</sub>), 33.0 (+, CH), 65.4 (+, CH), 69.4 (-, CH<sub>2</sub>), 165.8 (Cq).

(*S*)-*N*-Benzyl-4-*iso*-propyl-4,5-dihydrooxazol-2-amine (**82**)

To a solution of **75** (300 mg, 1.89 mmol, 2.0 equiv) in dry toluene *p*-TSA (16 mg, 0.09 mmol, 0.1 equiv) and *N*-benzylamine (103  $\mu$ l, 0.95 mmol, 1.0 equiv) were added and the mixture was heated to reflux for 1.5 h. The solvent was evaporated and the crude mixture was purified via flash chromatography (silica, EA) to yield **82** (174 mg, 0.80 mmol, 84%) as colorless crystals.

$R_f = 0.17$  (PE/EA = 1:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 0.79 (d, 3 H,  $J = 6.7$  Hz), 0.87 (d, 3 H,  $J = 6.7$  Hz), 1.62 (po, 1 H,  $J = 6.7$  Hz), 3.68-3.78 (m, 1 H), 3.89 (dd, 1 H,  $J = 7.9$  Hz, 6.8 Hz), 4.17 (dd, 1 H,  $J = 8.7$  Hz, 8.1 Hz), 4.29 (d, 1 H,  $J = 14.8$  Hz), 4.36 (d, 1 H,  $J = 14.8$  Hz), 4.90 (bs, 1 H), 7.16-7.33 (m, 5 H). – <sup>13</sup>C-NMR (101 MHz, CDCl<sub>3</sub>):  $\delta_C$  (ppm) = 17.8 (+, CH<sub>3</sub>), 18.9 (+, CH<sub>3</sub>), 33.2 (+, CH), 47.0 (-, CH<sub>2</sub>), 70.0 (+, CH), 70.4 (-, CH<sub>2</sub>), 127.2 (+, CH), 127.4 (+, CH), 128.5 (+, CH), 139.1 (Cq), 160.5 (Cq). – **mp** = 95 °C. – **IR** (neat):  $\tilde{\nu}$  (cm<sup>-1</sup>) = 3230, 3027, 2954, 2879, 1643, 1552, 1494, 1454, 1348, 1286, 1242, 1113, 1078, 1027, 974, 935, 729, 694, 585, 458. –  $[\alpha]_D^{20} = -38.3$  ( $c = 1$ , DCM). – **LRMS** (ESI):  $m/z = 219.1$  [M+H]<sup>+</sup>. – **HRMS** (ESI):  $m/z = 219.1493$  [M+H]<sup>+</sup>; calc. for [C<sub>13</sub>H<sub>19</sub>N<sub>2</sub>O]<sup>+</sup> = 219.1492.

### General procedure for small scale cyclopropanations of furan-3-carboxylic acid methyl ester **91** (GP-1):

Under nitrogen atmosphere a flame dried flask was charged with Cu(OTf)<sub>2</sub> (14.3 mg, 0.04 mmol, 0.01 equiv) and ligand (0.09 mmol, 0.022 equiv) in dry DCM (1 ml) and stirred for 30 minutes at room temperature. In a second flask under nitrogen atmosphere a solution of 3-methyl furoate **91** (500 mg, 3.97 mmol, 1.0 equiv) in dry DCM (2 ml) was prepared. This flask was cooled to the specified temperature and the solution of flask one was added in one portion through a syringe filter. A 5% (v/v) solution of phenylhydrazine in DCM (78  $\mu$ l, 0.04 mmol, 0.01 equiv) was added to the reaction mixture. *tert*-Butyldiazoacetate (solution in DCM; 1.5 equiv) was added by syringe pump. The mixture was stirred overnight, filtered through basic alumina and washed with DCM (200 ml). The solvent was evaporated in vacuo and the crude product was purified by flash chromatography (silica, PE/EA = 15:1) to provide **15** as a white solid that was recrystallized from *n*-pentane or *n*-heptane.

Cyclopropanation reactions on larger scale were performed according to **GP-1** with the exception that an electronically controlled dropping system was applied for the addition of larger amounts of the diazo compound, and PhNHNH<sub>2</sub> was added in pure form.

(1*S*,5*R*,6*S*)-6-*tert*-Butyl-4-methyl-2-oxabicyclo[3.1.0]hex-3-ene-4,6-dicarboxylate  
((*S*,*R*,*S*)-(-)-**15**)

According to **GP-1** **91** (12.91 g, 102.37 mmol, 1.0 equiv) was cyclopropanated with *tert*-butyldiazoacetate (171 g, 12.8 wt%, 1.5 equiv), Cu(OTf)<sub>2</sub> (370 mg, 1.02 mmol, 0.01 equiv), ligand **8** (602 mg, 2.25 mmol, 0.022 equiv) and neat PhNHNH<sub>2</sub> (101  $\mu$ l, 1.02 mmol, 0.01 equiv) in dry DCM (75 ml) to yield **15** (11.56 g, 448.13 mmol, 47%) as white solid.

$R_f$  = 0.30 (PE/EA = 15:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 1.00-1.04 (m, 1 H), 1.42 (s, 9 H), 3.00 (dd, 1 H,  $J$  = 5.6 Hz, 2.9 Hz), 3.73 (s, 3 H), 4.90-4.94 (m, 1 H), 7.16 (s, 1 H). – <sup>13</sup>C-NMR (101 MHz, CDCl<sub>3</sub>):  $\delta_C$  (ppm) = 22.5 (+, CH), 28.1 (+, CH<sub>3</sub>), 29.1, (+, CH), 51.5 (+, CH<sub>3</sub>), 68.9 (+, CH), 81.4 (Cq), 115.8 (Cq), 156.4 (+, CH), 164.2 (Cq), 170.8 (Cq). –

### General procedure for small scale cyclopropanations of *N*-Boc-pyrrole **101** (GP-2):

Under nitrogen atmosphere a flame dried flask was charged with Cu(OTf)<sub>2</sub> (10.8 mg, 0.03 mmol, 0.01 equiv) and ligand (0.06 mmol, 0.022 equiv) in dry DCM (1 ml) and stirred for 30 minutes at room temperature. In a second flask under nitrogen atmosphere a solution of *N*-Boc-pyrrole **101** (500 mg, 2.99 mmol, 1.0 equiv) in dry DCM (2 ml) was prepared. This flask was cooled to the specified temperature and the solution of flask one was added in one portion through a syringe filter. A 5% (v/v) solution of phenylhydrazine in DCM (59  $\mu$ l, 0.03 mmol, 0.01 equiv) was added to the reaction mixture. *tert*-Butyldiazoacetate (solution in DCM; 1.5 equiv) was added by syringe pump. The mixture was stirred overnight, filtered through basic alumina and washed with DCM (200 ml). The solvent was evaporated in vacuo and the crude product was purified by flash chromatography (silica, PE/EA = 50:1) to provide **103** as a white solid that was recrystallized from PE.

Cyclopropanation reactions on larger scale were performed according to **GP-2** with the exception that an electronically controlled dropping system was applied for the addition of larger amounts of the diazo compound, and PhNHNH<sub>2</sub> was added in pure form.

(1*S*,5*S*,6*S*)-di-*tert*-Butyl-2-azabicyclo[3.1.0]hex-3-ene-2,6-dicarboxylate ((*S,S,S*)-(-)-**103**)

According to **GP-2 101** (25.20 g, 150.60 mmol, 1.0 equiv) was cyclopropanated with *tert*-butyldiazoacetate (32.0 g, 11.1 wt%, 1.5 equiv), Cu(OTf)<sub>2</sub> (543 mg, 1.51 mmol, 0.01 equiv), ligand **8** (885 mg, 3.31 mmol, 0.022 equiv) and neat PhNHNH<sub>2</sub> (148 μl, 1.51 mmol, 0.01 equiv) in dry DCM (30 ml) at -15 °C to yield **103** (18.64 g, 66.26 mmol, 44%) as white solid. In addition, starting material **101** (3.78 g, 22.59 mmol, 15%) could be reisolated.

$R_f = 0.45$  (PE/EA = 10:1) – **<sup>1</sup>H-NMR** (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 0.87-0.88 (m, 1 H), 1.41 (s, 9 H, CH<sub>3</sub>), 1.47 (s, 9 H, CH<sub>3</sub>), 2.62-2.75 (m, 1 H), 4.12-4.40 (m, 1 H), 5.24-5.40 (m, 1 H), 6.32-6.58 (m, 1 H). – **<sup>13</sup>C-NMR** (101 MHz, CDCl<sub>3</sub>):  $\delta_C$  (ppm) = 23.9 (+, CH), 28.1 (+, CH<sub>3</sub>), 28.2 (+, CH<sub>3</sub>), 30.6 + 31.6 (+, CH), 43.7 + 44.0 (+, CH), 80.6 (Cq), 81.5 (Cq), 110.0 (+, CH), 129.4 + 129.6 (+, CH), 151.0 + 151.3 (Cq, CO), 172.0 + 172.3 (Cq, CO). (1*S*,5*S*,6*S*)-di-*tert*-Butyl-2-azabicyclo[3.1.0]hexane-2,6-dicarboxylate (**149**)

**Method A:** In a Schlenk flask **103** (143.5 mg, 0.51 mmol, 1.0 equiv) was dissolved in THF (6 ml) and Pd/C (10 wt%) was added. A balloon with hydrogen (1 atm) was attached and the atmosphere in the flask was flushed twice with hydrogen gas. The mixture was stirred under a hydrogen atmosphere at ambient temperature for 1.5 h. After completion the crude mixture was filtered through a plug of celite and concentrated in vacuo. The crude product was purified via flash chromatography (silica, PE/EA = 15:1) to afford **149** (122.5 mg, 0.43 mmol, 85%) as a white solid that can be recrystallized from PE.

**Method B:** To a solution of **103** (167.6 mg, 0.60 mmol, 1.0 equiv) in DCM Et<sub>3</sub>SiH (0.48 ml, 2.98 mmol, 5.0 equiv) and TFA (92  $\mu$ l, 1.19 mmol, 2.0 equiv) were added and the solution was stirred at ambient temperature for 6 h. After completion the volatiles were removed in vacuo and the crude mixture was purified via flash chromatography (silica, PE/EA = 15:1) to afford **149** (55.0 mg, 0.19 mmol, 33%) as a white solid.

(*S*)-2-(Pyrrolidin-3-yl)acetic acid ((*S*)-(+)-**109**)

Cyclopropane **149** (103.5 mg, 0.37 mmol, 1.0 equiv) was dissolved in dry DCM (5 ml) and Et<sub>3</sub>SiH (0.23 ml, 1.46 mmol, 4.0 equiv) and TFA (56 μl, 0.73 mmol, 2.0 equiv) were added. The reaction mixture was stirred at room temperature for 24 h. Then more TFA (112 μl, 1.46 mmol, 4.0 equiv) was added and the mixture stirred for another 48 h. After completion of the reaction (TLC) the volatiles were removed in vacuo to yield **109** as TFA salt. For removal of the counterion **109** was loaded onto a column with Dowex 50WX8-400 (preactivated with 0.1 M HCl). The resin was washed with water and finally eluted with 15% NH<sub>3</sub> (aq.). The fractions were then concentrated under reduced pressure and lyophilized to yield **109** (47.4 mg, 0.37 mmol, quant.) as a slightly beige-colored amorphous solid.

di-*tert*-Butyl-(1*S*,5*S*,6*S*)-3-(2,4,6-trimethoxyphenyl)-2-azabicyclo[3.1.0]hexane-2,6-dicarboxylate (**172**)

To a solution of **103** (152.8 mg, 0.54 mmol, 1.0 equiv) and 1,3,5-trimethoxybenzene (109.6 mg, 0.65 mmol, 1.2 equiv) in dry DCM TFA (50  $\mu$ l, 0.65 mmol, 1.2 equiv) was added and the reaction mixture was stirred for one hour at room temperature. Volatiles were removed in vacuo and the crude mixture was purified via flash chromatography (silica, PE/EA = 5:1) to yield **172** (32.7 mg, 0.07 mmol, 13%) as a pale yellow oil.

$R_f = 0.23$  (PE/EA = 5:1) –  **$^1H$ -NMR** (400 MHz,  $CDCl_3$ ):  $\delta_H$  (ppm) = 0.81-0.94 (m, 1 H), 1.02-1.31 (m, 9 H), 1.43 (s, 9 H), 2.09-2.31 (m, 2 H), 2.39 (dd, 1 H,  $J = 12.8$  Hz, 9.8 Hz), 3.72-3.83 (m, 9.4 H), 3.85-4.00 (m, 0.6 H), 4.94-5.31 (m, 1 H), 6.03-6.11 (m, 2 H). –  **$^{13}C$ -NMR** (101 MHz,  $CDCl_3$ ):  $\delta_C$  (ppm) = 25.3 (+, CH), 28.2 (+,  $CH_3$ ), 30.7 (+, CH), 34.9 (-,  $CH_2$ ), 46.1 (+, CH), 52.8 (+, CH), 55.3 (+,  $CH_3$ ), 55.6 (+,  $CH_3$ ), 79.1 (Cq), 80.2 (Cq), 90.5 (+, CH), 112.5 (Cq), 154.9 (Cq), 158.6 (Cq), 160.1 (Cq), 170.8 (Cq). – **IR** (neat):  $\tilde{\nu}$  ( $cm^{-1}$ ) = 2972, 2935, 2843, 1689, 1593, 1497, 1458, 1401, 1370, 1321, 1252, 1228, 1201, 1147, 1119, 1060, 1041, 978, 961, 951, 931, 918, 879, 845, 812, 754, 666. –  $[\alpha]_D^{20} = +23.5$  ( $c = 1$ ,  $CHCl_3$ ). – **LRMS** (ESI):  $m/z = 450.2 [M+H]^+$ ,  $472.2 [M+Na]^+$ ,  $921.5 [2M+Na]^+$ . – **HRMS** (ESI):  $m/z = 450.2493 [M+H]^+$ ; calc. for  $[C_{20}H_{35}N_2O_5]^+ = 450.2486$ .

(1*S*,2*S*,3*S*,4*S*,6*S*,7*S*)-*tert*-Butyl-3,7-bis(hydroxymethyl)-5-azatricyclo[4.1.0.02,4]heptane-5-carboxylate (**178**)[205]

To a suspension of LAH (285 mg, 10.14 mmol, 2.0 equiv) in dry THF (65 ml) **104** (2.01 g, 5.07 mmol, 1.0 equiv) was added portion wise at 0 °C and the solution was stirred for 22 h in the defrosting ice bath. After complete consumption of the starting material the reaction was quenched by the addition of EA and NH<sub>4</sub>Cl (sat.) solution. The aqueous layer was extracted with EA and the organic layers combined and dried over Na<sub>2</sub>SO<sub>4</sub>. After evaporation of the solvent the crude mixture was purified by a short silica column (100% EA → 100% MeOH; hereby dissolved silica was filtered from the product from a CHCl<sub>3</sub> solution) to yield **178** as a white solid<sup>12</sup> (1.22 g, 4.79 mmol, 95%).

$R_f = 0.14$  (EA) – **<sup>1</sup>H-NMR** (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 1.17-1.30 (m, 2 H), 1.42 (s, 9 H, Boc), 1.59 (dd, 1 H,  $J = 6.4$  Hz, 3.7 Hz), 1.69 (dd, 1 H,  $J = 6.4$  Hz, 3.7 Hz), 2.78 (d, 1 H,  $J = 6.3$  Hz), 2.87 (d, 1 H,  $J = 6.3$  Hz), 3.15 (dd, 1 H,  $J = 11.6$  Hz, 8.4 Hz), 3.25 (dd, 1 H,  $J = 11.4$  Hz, 7.7 Hz), 3.33-3.56 (m, 3 H), 4.24 (bs, 1 H, OH). – **<sup>13</sup>C-NMR** (101 MHz, CDCl<sub>3</sub>):  $\delta_C$  (ppm) = 23.9 (+, CH), 25.4 (+, CH), 28.5 (+, CH<sub>3</sub>), 29.3 + 29.5 (+, CH), 39.2 + 39.8 (+, CH), 61.9 + 62.0 (-, CH<sub>2</sub>), 80.3 (Cq), 155.9 (Cq). – **mp** = 78 °C – **LRMS** (ESI):  $m/z = 256.2$  [M+H]<sup>+</sup>, 278.1 [M+Na]<sup>+</sup>, 511.3 [2M+H]<sup>+</sup>, 533.3 [2M+Na]<sup>+</sup>. – **HRMS** (ESI):  $m/z = 256.1536$  [M+H]<sup>+</sup>; calc. for [C<sub>13</sub>H<sub>22</sub>NO<sub>4</sub>]<sup>+</sup> = 256.1543.

((1*S*,2*S*,3*S*,4*S*,6*S*,7*S*)-5-(*tert*-Butoxycarbonyl)-5-azatricyclo[4.1.0.02,4]heptane-3,7-diyl)bis(methylene) diacetate (**187**)

<sup>12</sup> Reported as colorless foam (no mp given).

Diol **178** (77.4 mg, 0.30 mmol, 1.0 equiv) was dissolved in DCM (5 ml) and cooled to 0 °C. DMAP (7 mg, 0.06 mmol, 0.2 equiv), Ac<sub>2</sub>O (172 µl, 1.82 mmol, 6.0 equiv) and NEt<sub>3</sub> (252 µl, 1.82 mmol, 6.0 equiv) were added and the reaction mixture was stirred for 15 min at 0 °C. After quenching the reaction mixture with sat. NH<sub>4</sub>Cl solution, the aqueous layer was extracted with DCM (4 x). Finally, the combined organic layers were washed with sat. NaHCO<sub>3</sub> (1 x) and brine (1 x) and dried over Na<sub>2</sub>SO<sub>4</sub>. After evaporation of the solvent the crude product was purified by flash chromatography (silica, PE/EA = 5:1 → 100% EA) to yield **187** (93.6 mg, 0.28 mmol, 91%) as a colorless oil that crystallizes slowly.

$R_f$  = 0.16 (PE/EA = 5:1) – **<sup>1</sup>H-NMR** (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 1.22-1.34 (m, 2 H), 1.42 (s, 9 H, CH<sub>3</sub>, Boc), 1.65-1.74 (m, 2 H), 2.01 (s, 6 H, CH<sub>3</sub>), 2.83 (d, 1 H,  $J$  = 6.4 Hz), 3.03 (d, 1 H,  $J$  = 6.43 Hz), 3.70 (dd, 1 H,  $J$  = 11.7 Hz, 8.3 Hz), 3.81 (dd, 1 H,  $J$  = 7.7 Hz, 2.4 Hz), 3.97 (dd, 1 H,  $J$  = 11.8 Hz, 6.5 Hz). – **<sup>13</sup>C-NMR** (101 MHz, CDCl<sub>3</sub>):  $\delta_C$  (ppm) = 21.0 (+, CH<sub>3</sub>), 24.3 (+, CH), 25.4 + 25.7 (+, CH), 26.0 (+, CH), 28.4 (+, CH<sub>3</sub>), 39.3 (+, CH), 63.8 + 63.9 (-, CH<sub>2</sub>), 79.9 (Cq), 155.2 (Cq), 171.0 + 171.1 (Cq). – **IR** (neat):  $\tilde{\nu}$  (cm<sup>-1</sup>) = 2976, 1737, 1695, 1435, 1393, 1365, 1328, 1226, 1176, 1123, 1030, 972, 851, 763, 632, 539, 497, 462, 399. – **LRMS** (ESI):  $m/z$  = 284.1 [M+H-C<sub>4</sub>H<sub>8</sub>]<sup>+</sup>, 340.2 [M+H]<sup>+</sup>, 362.2 [M+Na]<sup>+</sup>, 701.3 [2M+Na]<sup>+</sup>. – **HRMS** (ESI):  $m/z$  = 340.1754 [M+H]<sup>+</sup>; calc. for [C<sub>17</sub>H<sub>26</sub>NO<sub>6</sub>]<sup>+</sup> = 340.1755.

(3aR,3bR,6aR,7aR)-*tert*-Butyl-6a,7a-dihydro-3aH-difuro[2,3-b:3',2'-d]pyrrole-7(3bH)-carboxylate (**179**)[205]

Diol **178** (476 mg, 1.87 mmol, 1.0 equiv) was dissolved in DMSO (32 ml) and IBX (1.15 g, 4.10 mmol, 2.2 equiv) was added. The reaction mixture was stirred at room temperature for 64 h until the starting material vanished completely (TLC control). The mixture was treated with water and extracted with EA (5 x). The combined organic layers were washed with water and dried over Na<sub>2</sub>SO<sub>4</sub>. After evaporation of the solvent the crude product was purified by flash chromatography (silica, PE/EA = 7:1) to yield **179** (242 mg, 0.96 mmol, 52%) as a colorless oil.

$R_f = 0.38$  (PE/EA = 5:1) –  $^1\text{H-NMR}$  (300 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{H}}$  (ppm) = 1.48 (s, 9 H,  $\text{CH}_3$ ), 3.43 (d, 2 H,  $J = 6.6$  Hz), 4.85-4.89 (m, 2 H), 5.95-6.16 (m, 2 H), 6.21 (bs, 2 H). –  $^{13}\text{C-NMR}$  (101 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{C}}$  (ppm) = 28.2 (+,  $\text{CH}_3$ ), 51.3 + 51.4 (+, CH), 81.2 (Cq), 92.4 (+, CH), 102.9 (+, CH), 144.6 + 144.7 (+, CH), 153.3 (Cq). – **LRMS** (ESI):  $m/z = 196.1$  [ $\text{M}+\text{H}-\text{C}_4\text{H}_8$ ] $^+$ , 252.1 [ $\text{M}+\text{H}$ ] $^+$ , 274.1 [ $\text{M}+\text{Na}$ ] $^+$ , 525.2 [ $2\text{M}+\text{Na}$ ] $^+$ . – **HRMS** (ESI):  $m/z = 252.1237$  [ $\text{M}+\text{H}$ ] $^+$ ; calc. for [ $\text{C}_{13}\text{H}_{18}\text{NO}_4$ ] $^+$  = 252.1230.

Methyl-2-(*N*-(*tert*-butoxycarbonyl)formamido)-3-formylcyclopropane-1-carboxylate  
((±)-**218**)[275]

Cyclopropane (±)-**18** (402 mg, 1.68 mmol, 1.0 equiv) was dissolved in DCM (45 ml) and cooled to  $-78$  °C. Then ozone was bubbled through the solution until a characteristic blue color persisted (~ 15 min). After completion, oxygen was bubbled through the solution to displace excess ozone until the blue color vanished (~ 10 min). The gas inlet was removed, DMS (0.61 ml, 8.40 mmol, 5.0 equiv) was added and the solution was stirred overnight in the defrosting cooling bath. The reaction mixture was then concentrated under reduced pressure and purified via flash chromatography (silica, PE/EA = 3:1) to yield (±)-**218** (440 mg, 1.62 mmol, 97%) as a colorless oil that slowly crystallized in the freezer.

$R_f = 0.35$  (PE/EA = 3:1) –  $^1\text{H-NMR}$  (300 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{H}}$  (ppm) = 1.52 (s, 9 H,  $\text{CH}_3$ ), 2.75 (dd, 1 H,  $J = 5.9$  Hz, 4.8 Hz), 2.92-2.99 (m, 1 H), 3.21 (dd, 1 H,  $J = 8.0$  Hz, 4.8 Hz), 3.75 (s, 3 H,  $\text{CH}_3$ ), 9.07 (s, 1 H), 9.54 (d, 1 H,  $J = 2.4$  Hz).

2-(*N*-(*tert*-Butoxycarbonyl)formamido)-3-(methoxycarbonyl)cyclopropane-1-carboxylic acid ((±)-**219**)[275]

Cyclopropane (±)-**218** (440 mg, 1.62 mmol, 1.0 equiv) was dissolved in MeCN (5 ml) and cooled to 0 °C. After that KH<sub>2</sub>PO<sub>4</sub> (132 mg, 0.97 mmol, 0.6 equiv) in water (1 ml), H<sub>2</sub>O<sub>2</sub> (0.16 ml, 5.35 mmol, 3.3 equiv) and NaClO<sub>2</sub> (322 mg, 3.56 mmol, 2.2 equiv) in water (3 ml) were added and the reaction mixture was stirred for 2.5 h at 0 °C until gas evolution ceased. Then Na<sub>2</sub>SO<sub>3</sub> (0.8 equiv) was added and the solution was stirred for one additional hour at 0 °C. The reaction mixture was then acidified with 1 M KHSO<sub>4</sub> (pH 1-2), the phases were separated and the aqueous layer was extracted with EA (5 x). The combined organic layers were dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated in vacuo to yield (±)-**219** (467 mg, 1.63 mmol, quant.) as a white solid.

$R_f = 0.11$  (PE/EA = 2:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 1.52 (s, 9 H, CH<sub>3</sub>), 2.56-2.68 (m, 2 H), 3.22 (dd, 1 H,  $J = 7.7$  Hz, 5.1 Hz), 3.77 (s, 3 H, CH<sub>3</sub>), 7.86 (bs, 1 H), 9.13 (s, 1 H).

2-((*tert*-Butoxycarbonyl)amino)-3-(methoxycarbonyl)cyclopropane-1-carboxylic acid ((±)-**33**)[275]

Cyclopropane (±)-**219** (467 mg, 1.63 mmol, 1.0 equiv) was dissolved in MeCN (5 ml), DEAEA (0.47 ml, 3.34 mmol, 2.05 equiv) was added and the reaction mixture was stirred at room temperature for 28 h. The mixture was concentrated under reduced pressure, EA was added and the pH of the solution was adjusted to pH 2 with 1 M KHSO<sub>4</sub>. The aqueous layer was extracted with EA (4 x) and the combined organic layers were dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated in vacuo to yield (±)-**33** (348 mg, 1.34 mmol, 82%) as a white solid.

$^1\text{H-NMR}$  (300 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{H}}$  (ppm) = 1.46 (s, 9 H,  $\text{CH}_3$ ), 2.22-2.57 (m, 2 H), 3.62-3.99 (m, 4 H), 5.45 + 6.54 (bs, 1 H).

1-Benzyl-2-methyl-3-((*tert*-butoxycarbonyl)amino)cyclopropane-1,2-dicarboxylate  
(( $\pm$ )-**220**)[275]

Cyclopropane ( $\pm$ )-**33** (348 mg, 1.34 mmol, 1.0 equiv) was dissolved in DMF (5 ml),  $\text{NaHCO}_3$  (225 mg, 2.68 mmol, 2.0 equiv) and  $\text{BnBr}$  (175  $\mu\text{l}$ , 1.47 mmol, 1.1 equiv) were added and the mixture was stirred at room temperature for 48 h. EA (10 ml) and water (10 ml) were added, the phases separated and the aqueous layer was extracted with EA (4 x). The combined organic layers were washed with water (2 x), dried over  $\text{Na}_2\text{SO}_4$ , filtered and concentrated in vacuo. Flash chromatography (silica, PE/EA = 5:1) yielded pure ( $\pm$ )-**220** (429 mg, 1.23 mmol, 92%) as a white solid.

$R_f$  = 0.27 (PE/EA = 5:1) –  $^1\text{H-NMR}$  (300 MHz,  $\text{CDCl}_3$ ):  $\delta_{\text{H}}$  (ppm) = 1.44 (s, 9 H,  $\text{CH}_3$ ), 2.24-2.31 (m, 1 H), 2.52 (dd, 1 H,  $J$  = 8.3 Hz, 5.2 Hz), 3.69 (s, 3 H,  $\text{CH}_3$ ), 3.76-3.95 (m, 1 H), 5.12 (d, 1 H,  $J$  = 12.2 Hz), 5.21 (d, 1 H,  $J$  = 12.2 Hz), 5.53 (bs, 1 H), 7.30-7.42 (m, 5 H).

1-Benzyl-2-methyl-(1*R*,2*R*,3*S*)-3-((*S*)-pyrrolidine-2-carboxamido)cyclopropane-1,2-dicarboxylate (**221a**)

1-Benzyl-2-methyl-(1*S*,2*S*,3*R*)-3-((*S*)-pyrrolidine-2-carboxamido)cyclopropane-1,2-dicarboxylate (**221b**)

Racemic  $\beta$ -ACC ( $\pm$ )-**220** (4.38 g, 12.54 mmol, 1.0 equiv) was dissolved in dry EA (10 ml) and cooled to 0 °C. A solution of HCl in EA (4.2 M, 45 ml) was added and the reaction mixture was stirred at 0 °C until starting material was fully consumed (4 h; TLC analysis). Volatiles were removed in vacuo and the resulting white (pinkish) residue was treated with a premixed solution of *N*-Boc-*L*-proline (3.37 g, 15.68 mmol, 1.25 equiv) and EDC•HCl (3.00 g, 15.68 mmol, 1.25 equiv) in DCM. Finally, triethylamine (2.17 ml, 15.68 mmol, 1.25 equiv) was added and the reaction was stirred at room temperature overnight (17 h). The crude reaction mixture treated with water (50 ml), the pH was adjusted to pH 3 by the addition of 1M KHSO<sub>4</sub> and the aqueous layer was extracted with DCM (4 x). The combined organic layers were then washed with NaHCO<sub>3</sub> (sat. 1 x) and brine (1 x), dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated in vacuo. The crude was purified via flash chromatography (silica, PE/EA = 2:1) to yield a mixture of two *N*-Boc protected diastereomeric dipeptides Boc-Pro-▲/▼-OBn (4.13 g, 9.24 mmol, 74%) as a white foam. The mixture of diastereomers Boc-Pro-▲/▼-OBn (4.70 g, 10.53 mmol, 1.0 equiv) was deprotected with a solution of HCl in EA (4.2 M, 50 ml) at 0 °C and the two diastereomers were separated via flash chromatography (silica, DCM/MeOH = 15:1) to yield **221a** (1.57 g, 4.54 mmol, 43%) and **221b** (1.21 g, 3.49 mmol, 33%).

**221a (major):**  $R_f$  = 0.49 (DCM/MeOH = 9:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 1.50-1.69 (m, 2 H), 1.73-1.91 (m, 1 H), 1.94-2.08 (m, 2 H), 2.26-2.34 (m, 1 H), 2.45-2.54 (m, 1 H), 2.71-2.96 (m, 2 H), 3.53-3.68 (m, 4 H), 3.94-4.08 (m, 1 H), 5.00-5.17 (m, 2 H), 7.23-7.33 (m, 5 H), 8.36 (d, 1 H,  $J$  = 8.4 Hz).

**221b (minor):**  $R_f$  = 0.29 (DCM/MeOH = 9:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>):  $\delta_H$  (ppm) = 1.44-1.64 (m, 2 H), 1.69-1.83 (m, 1 H), 1.93-2.10 (m, 2 H), 2.30-2.36 (m, 1 H), 2.48-2.55 (m, 1 H), 2.65-2.67 (m, 1 H), 2.84-2.96 (m, 1 H), 3.60-3.71 (m, 4 H), 3.94-4.03 (m, 1 H), 5.04-5.15 (m, 2 H), 7.25-7.34 (m, 5 H), 8.41 (d, 1 H,  $J$  = 8.2 Hz).

*tert*-Butyl-(*S*)-2-(((1*R*,2*R*,3*R*)-2-((*S*)-2-((benzyloxy)carbonyl)pyrrolidine-1-carbonyl)-3-(methoxycarbonyl)cyclopropyl)carbamoyl)pyrrolidine-1-carboxylate (**222a**)

Dipeptide **221a** (271 mg, 0.78 mmol, 1.0 equiv) and Boc<sub>2</sub>O (179 mg, 0.82 mmol, 1.05 equiv) were dissolved in dry DCM (5 ml). A solution of DMAP (10 mg, 0.08 mmol, 0.1 equiv) and NEt<sub>3</sub> (81 μl, 0.59 mmol, 0.75 equiv) in dry DCM (5 ml) was added dropwise, and the reaction mixture was stirred at room temperature for 16 h. The reaction was quenched with water and then acidified with 1 M KHSO<sub>4</sub> (pH 2-3). After extraction with DCM (3 x), the combined organic layers were washed with brine (1 x), dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated in vacuo to yield the *N*-Boc protected dipeptide Boc-Pro-▲-OBn (328 mg, 0.73 mmol, 94%). The protected dipeptide Boc-Pro-▲-OBn (1.78 g, 3.98 mmol, 1.0 equiv) was dissolved in MeOH (50 ml), Pd/C (10%) was added and a balloon of hydrogen gas (1 atm) was mounted to the flask. The atmosphere was flushed with hydrogen gas to remove air and the mixture was stirred at room temperature for 5 h. After filtration of the reaction mixture through a plug of Celite and washing with MeOH, the solvent was removed in vacuo to yield the free acid Boc-Pro-▲-OH (1.44 g, quant.). Boc-Pro-▲-OH (284 mg, 0.76 mmol, 1.0 equiv) and EDC•HCl (153 mg, 0.80 mmol, 1.05 equiv) were dissolved in dry DCM (12 ml) and stirred for 30 min at room temperature. H-Pro-OBn•HCl (221 mg, 0.91 mmol, 1.2 equiv) and NEt<sub>3</sub> (127 μl, 0.91 mmol, 1.2 equiv) were added and the reaction mixture was stirred for 48 h. Water (10 ml) and DCM (10 ml) were added and the pH was adjusted to pH 4 with 1 M KHSO<sub>4</sub>. The organic layer was then washed with NaHCO<sub>3</sub> (sat. 1 x) and brine (1 x), dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated in vacuo. The crude mixture was purified via flash chromatography (silica, DCM/MeOH = 49:1) to yield **222a** (255 mg, 0.47 mmol, 62%) as a colorless foam.

**R<sub>f</sub>** = 0.36 (DCM/MeOH = 19:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>): δ<sub>H</sub> (ppm) = 1.43 (s, 9 H), 1.74-2.29 (m, 8 H), 2.29-2.42 (m, 1 H), 2.49-2.71 (m, 1 H), 3.22-3.59 (m, 2 H), 3.59-3.90 (m, 5 H), 4.01-4.35 (m, 2 H), 4.41-4.63 (m, 1 H), 5.04-5.29 (m, 2 H), 7.28-7.83 (m, 6 H).

*tert*-Butyl-(*S*)-2-(((1*S*,2*S*,3*S*)-2-((*S*)-2-((benzyloxy)carbonyl)pyrrolidine-1-carbonyl)-3-(methoxycarbonyl)cyclopropyl)carbamoyl)pyrrolidine-1-carboxylate (**222b**)

Dipeptide **221b** (1.21 g, 3.49 mmol, 1.0 equiv) and Boc<sub>2</sub>O (800 mg, 3.67 mmol, 1.05 equiv) were dissolved in dry DCM (20 ml). A solution of DMAP (43 mg, 0.35 mmol, 0.1 equiv) and NEt<sub>3</sub> (0.36 ml, 2.62 mmol, 0.75 equiv) in dry DCM (20 ml) was added dropwise, and the reaction mixture was stirred at room temperature for 24 h. The reaction was quenched with water and then acidified with 1 M KHSO<sub>4</sub> (pH 2-3). After extraction with DCM (3 x), the combined organic layers were washed with brine (1 x), dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated in vacuo to yield the *N*-Boc protected dipeptide Boc-Pro-▼-OBn (1.49 g, 3.33 mmol, 95%). The protected dipeptide Boc-Pro-▼-OBn (570 mg, 1.28 mmol, 1.0 equiv) was dissolved in MeOH (15 ml), Pd/C (10%) was added and a balloon of hydrogen gas (1 atm) was mounted to the flask. The atmosphere was flushed with hydrogen gas to remove air and the mixture was stirred at room temperature for 1 h. After filtration of the reaction mixture through a plug of Celite and washing with MeOH, the solvent was removed in vacuo to yield the free acid Boc-Pro-▼-OH (485 mg, quant.). Boc-Pro-▼-OH (458 mg, 1.28 mmol, 1.0 equiv) and EDC•HCl (257 mg, 1.34 mmol, 1.05 equiv) were dissolved in dry DCM (20 ml) and stirred for 30 min at room temperature. H-Pro-OBn•HCl (370 mg, 1.53 mmol, 1.2 equiv) and NEt<sub>3</sub> (212 μl, 1.53 mmol, 1.2 equiv) were added and the reaction mixture was stirred for 48 h. Water (10 ml) and DCM (10 ml) were added and the pH was adjusted to pH 4 with 1 M KHSO<sub>4</sub>. The organic layer was then washed with NaHCO<sub>3</sub> (sat. 1 x) and brine (1 x), dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated in vacuo. The crude mixture was purified via flash chromatography (silica, DCM/MeOH = 49:1) to yield **222b** (395 mg, 0.73 mmol, 57%) as a colorless foam.

$R_f = 0.32$  (DCM/MeOH = 19:1) – <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>): δ<sub>H</sub> (ppm) = 1.45 (s, 9 H), 1.73-1.93 (m, 3 H), 1.93-2.25 (m, 5 H), 2.28-2.39 (m, 1 H), 2.49-2.65 (m, 1 H), 3.18-3.55 (m,

2 H), 3.56-3.76 (m, 4 H), 3.78-3.95 (m, 1 H), 4.04-4.34 (m, 2 H), 4.46-4.58 (m, 1 H), 5.03-5.26 (m, 2 H), 7.28-7.61 (m, 6 H).

(*S*)-1-((1*R*,2*R*,3*R*)-2-(Methoxycarbonyl)-3-((*S*)-pyrrolidine-2-carboxamido)cyclopropanecarbonyl)pyrrolidine-2-carboxylic acid (**217a**)[58, 240]

Orthogonally protected tripeptide **222a** (154 mg, 0.28 mmol, 1.0 equiv) was deprotected with a solution of HCl in EA (4.2 M, 4 ml) at 0 °C for 1.5 h. The volatiles were removed in vacuo and the residue was treated with water (5 ml) and extracted with Et<sub>2</sub>O (2 x). The pH of the aqueous layer was adjusted to pH 9 by the use of NaHCO<sub>3</sub> (sat.) and then extracted with DCM (4 x). The combined organic layers were dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated in vacuo to yield H-Pro-▲-Pro-OBn (116 mg, 0.26 mmol, 93%) as white foam. H-Pro-▲-Pro-OBn (116 mg, 0.26 mmol, 1.0 equiv) was dissolved in MeOH (5 ml), Pd/C (10%) was added and a balloon of hydrogen gas (1 atm) was mounted to the flask. The atmosphere was flushed with hydrogen gas to remove air and the mixture was stirred at room temperature for 1 h. After filtration of the reaction mixture through a plug of Celite and washing with MeOH, the solvent was removed in vacuo to yield **217a** (106 mg, quant.) as white amorphous solid.

$R_f = 0.04$  (DCM/MeOH = 4:1) – <sup>1</sup>H-NMR (300 MHz, MeOD):  $\delta_H$  (ppm) = 1.75-2.13 (m, 6 H), 2.13-2.43 (m, 2 H), 2.43-2.72 (m, 2 H), 3.36-3.46 (m, 1 H), 3.53 (dd, 1 H,  $J = 7.9$  Hz, 4.5 Hz), 3.55-3.66 (m, 1 H), 3.63-4.01 (m, 5 H), 4.19-4.68 (m, 2 H). – <sup>13</sup>C-NMR (101 MHz, MeOD):  $\delta_C$  (ppm) = 25.0 (-, CH<sub>2</sub>), 25.4 (-, CH<sub>2</sub>), 26.7 (+, CH), 28.0 (+, CH), 28.7 (+, CH), 30.9 (+, CH), 31.0 (-, CH<sub>2</sub>), 31.2 (-, CH<sub>2</sub>), 36.1 (+, CH), 36.6 (+, CH), 47.6 (-, CH<sub>2</sub>), 49.1 (-, CH<sub>2</sub>), 53.1 (+, CH<sub>3</sub>), 60.8 (+, CH), 62.2 (+, CH), 167.7 (Cq, CO), 171.1 (Cq, CO), 171.4 (Cq, CO, minor), 172.1 (Cq, CO, minor), 172.3 (Cq, CO), 175.8 (Cq, COOH). (signal doubling due to rotamers).

(*S*)-1-((1*S*,2*S*,3*S*)-2-(Methoxycarbonyl)-3-((*S*)-pyrrolidine-2-carboxamido)cyclopropanecarbonyl)pyrrolidine-2-carboxylic acid (**217b**)[58, 240]

Orthogonally protected tripeptide **222b** (322 mg, 0.59 mmol, 1.0 equiv) was deprotected with a solution of HCl in EA (4.2 M, 10 ml) at 0 °C for 3 h. The volatiles were removed in vacuo and the residue was treated with water (10 ml) and extracted with Et<sub>2</sub>O (1 x). The pH of the aqueous layer was adjusted to pH 8-9 by the use of NaHCO<sub>3</sub> (sat.) and then extracted with DCM (4 x). The combined organic layers were dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and concentrated in vacuo to yield H-Pro-▼-Pro-OBn (259 mg, 0.58 mmol, 99%) as white foam. H-Pro-▼-Pro-OBn (259 mg, 0.58 mmol, 1.0 equiv) was dissolved in MeOH (10 ml), Pd/C (10%) was added and a balloon of hydrogen gas (1 atm) was mounted to the flask. The atmosphere was flushed with hydrogen gas to remove air and the mixture was stirred at room temperature for 1.5 h. After filtration of the reaction mixture through a plug of Celite and washing with MeOH, the solvent was removed in vacuo to yield **217b** (223 mg, quant.) as white amorphous solid.

$R_f = 0.07$  (DCM/MeOH = 4:1) – **<sup>1</sup>H-NMR** (300 MHz, MeOD):  $\delta_H$  (ppm) = 1.82-1.94 (m, 1 H), 1.94-2.10 (m, 6 H), 2.31-2.42 (m, 1 H), 2.62 (dd, 1 H,  $J = 5.2$  Hz, 4.3 Hz), 2.71 (dd, 1 H,  $J = 8.2$  Hz, 5.3 Hz), 3.32-3.42 (m, 2 H), 3.65-3.71 (m, 2 H), 3.72 (s, 3 H), 3.92-4.02 (m, 1 H), 4.18 (dd, 1 H,  $J = 8.6$  Hz, 6.9 Hz), 4.36 (dd, 1 H,  $J = 8.4$  Hz, 2.3 Hz). – **<sup>13</sup>C-NMR** (101 MHz, MeOD):  $\delta_C$  (ppm) = 25.2 (-, CH<sub>2</sub>), 25.3 (-, CH<sub>2</sub>), 25.9 (+, CH), 30.6 (-, CH<sub>2</sub>), 30.7 (-, CH<sub>2</sub>), 31.0 (+, CH), 36.1 (+, CH), 47.5 (-, CH<sub>2</sub>), 48.5 (-, CH<sub>2</sub>), 52.9 (+, CH<sub>3</sub>), 61.2 (+, CH), 61.8 (+, CH), 166.2 (Cq), 171.6 (Cq), 172.4 (Cq), 177.2 (Cq). (signal doubling due to rotamers).

**General procedure for organocatalytic aldol reactions under ambient- and high-pressure conditions:**

To a solution of *para*-nitrobenzaldehyde **224** (30.2 mg, 0.2 mmol, 1.0 equiv) in 2 ml of acetone/water (10:1 (v/v)) catalyst **217a** (7.1 mg, 0.02 mmol, 0.1 equiv) was added and the solution was stirred for the indicated time at room temperature. Acetone was removed in vacuo and the residue was treated with EA (5 ml) and water (2 ml). After separation of the phases the organic layer was washed with water (1 ml), dried over Na<sub>2</sub>SO<sub>4</sub>, filtered and evaporated under reduced pressure. The aqueous layer was washed with diethylether (2 ml) and then lyophilized in order to recover the catalyst. On the other hand, the crude reaction mixture was purified via flash chromatography (silica, PE/EA = 2:1) and the product was analyzed by chiral HPLC.

For reactions under high pressure the prepared reaction mixture was transferred into a PTFE tube that was subsequently sealed by melting the tube and then incorporated into the high-pressure apparatus. Pressure was generated and maintained for the indicated time period without agitation of the reaction mixture.

(*R*)-4-Hydroxy-4-(4-nitrophenyl)butan-2-one (**225**)[58]

**R<sub>f</sub>** = 0.17 (PE/EA = 2:1) – **<sup>1</sup>H-NMR** (300 MHz, CDCl<sub>3</sub>): δ<sub>H</sub> (ppm) = 2.22 (s, 3 H), 2.82-2.87 (m, 2 H), 3.60 (bs, 1 H), 5.26 (dd, 1 H, *J* = 7.4 Hz, 4.9 Hz), 7.49-7.57 (m, 2 H), 8.16-8.23 (m, 2 H). – **HPLC analysis** (Chiralcel AS-H, *n*-heptane/*i*PrOH 99:1, 0.5 ml/min, 254 nm) *t<sub>r</sub>* = 18.97 min (*R*), *t<sub>r</sub>* = 22.38 min (*S*).

(*S*)-5-(((*R*)-1-Amino-1-oxopropan-2-yl)amino)-4-((1*S*,2*R*)-2-((1*R*,2*S*)-2-((*R*)-2-((*S*)-6-amino-2-((1*S*,2*R*)-2-((1*R*,2*S*)-2-((*R*)-2-((*S*)-5-amino-2-((1*S*,2*R*)-2-((1*R*,2*S*)-2-((*R*)-2-aminopropanamido)cyclopent-3-ene-1-carboxamido)cyclopentane-1-carboxamido)-5-oxopentanamido)propanamido)cyclopent-3-ene-1-carboxamido)cyclopentane-1-carboxamido)hexanamido)propanamido)cyclopent-3-ene-1-carboxamido)cyclopentane-1-carboxamido)-5-oxopentanoic acid (**226**)[256]

Foldamer **226** was obtained from solid phase synthesis on TentaGel R RAM resin via Fmoc/*t*Bu strategy. For synthesis and purification details as well as spectroscopic data of **226** see refs. [256, 257].

### 3 X-ray crystallographic data

(1*S*,5*S*,6*S*)-di-*tert*-Butyl-2-azabicyclo[3.1.0]hex-3-ene-2,6-dicarboxylate ((*S,S,S*)-(-)-**103**)

**Table 1.** Crystal data and structure refinement for (*S,S,S*)-(-)-**103**.

Empirical formula	C <sub>15</sub> H <sub>23</sub> NO <sub>4</sub>
Formula weight	281.34
Temperature/K	123.0
Crystal system	monoclinic
Space group	P2 <sub>1</sub>
<i>a</i> /Å	9.4639(3)
<i>b</i> /Å	6.1799(2)
<i>c</i> /Å	13.1692(5)
$\alpha$ /°	90
$\beta$ /°	90.131(4)
$\gamma$ /°	90
Volume/Å <sup>3</sup>	770.21(5)
<i>Z</i>	2
$\rho_{\text{calc}}$ /mg/mm <sup>3</sup>	1.213
<i>m</i> /mm <sup>-1</sup>	0.715
<i>F</i> (000)	304.0
Crystal size/mm <sup>3</sup>	0.53 × 0.081 × 0.0264
Radiation	CuK $\alpha$ ( $\lambda$ = 1.54184)
2 $\Theta$ range for data collection	6.72 to 149.3°
Index ranges	-11 ≤ <i>h</i> ≤ 11, -6 ≤ <i>k</i> ≤ 7, -16 ≤ <i>l</i> ≤ 14
Reflections collected	3296
Independent reflections	2115 [ <i>R</i> <sub>int</sub> = 0.0341, <i>R</i> <sub>sigma</sub> = 0.0469]

Data/restraints/parameters	2115/1/187
Goodness-of-fit on $F^2$	1.104
Final R indexes [ $I \geq 2\sigma(I)$ ]	$R_1 = 0.0610$ , $wR_2 = 0.1569$
Final R indexes [all data]	$R_1 = 0.0630$ , $wR_2 = 0.1602$
Largest diff. peak/hole / $e \text{ \AA}^{-3}$	0.36/-0.29
Flack parameter	0.0(3)

**Table 2.** Fractional atomic coordinates ( $\times 10^4$ ) and equivalent isotropic displacement parameters ( $\text{\AA}^2 \times 10^3$ ) for  $(S,S,S)$ -(-)-**103**.  $U_{\text{eq}}$  is defined as 1/3 of the trace of the orthogonalised  $U_{ij}$  tensor.

(1*S*,2*S*,3*S*,4*S*,6*S*,7*S*)-tri-*tert*-Butyl-5-azatricyclo[4.1.0.0<sup>2,4</sup>]heptane-3,5,7-tricarboxylate (**104**)

**Table 1.** Crystal data and structure refinement for **104**.

Empirical formula	C <sub>21</sub> H <sub>33</sub> NO <sub>6</sub>
Formula weight	395.48
Temperature/K	123.0
Crystal system	monoclinic
Space group	P2 <sub>1</sub> /c
<i>a</i> /Å	5.7733(2)
<i>b</i> /Å	9.1531(4)
<i>c</i> /Å	41.7797(19)
$\alpha$ /°	90
$\beta$ /°	91.716(4)
$\gamma$ /°	90
Volume/Å <sup>3</sup>	2206.80(16)
<i>Z</i>	4
$\rho_{\text{calc}}$ /mg/mm <sup>3</sup>	1.190
$\mu$ /mm <sup>-1</sup>	0.708
<i>F</i> (000)	856.0
Crystal size/mm <sup>3</sup>	0.3002 × 0.1264 × 0.0446
Radiation	CuK $\alpha$ ( $\lambda$ = 1.54184)
2 $\theta$ range for data collection	8.46 to 150.78°
Index ranges	-7 ≤ <i>h</i> ≤ 5, -11 ≤ <i>k</i> ≤ 10, -52 ≤ <i>l</i> ≤ 51
Reflections collected	8423
Independent reflections	4381 [R <sub>int</sub> = 0.0306, R <sub>sigma</sub> = 0.0357]
Data/restraints/parameters	4381/0/262

Goodness-of-fit on $F^2$	1.037
Final R indexes [ $I > 2\sigma(I)$ ]	$R_1 = 0.0498$ , $wR_2 = 0.1337$
Final R indexes [all data]	$R_1 = 0.0564$ , $wR_2 = 0.1421$
Largest diff. peak/hole / $e \text{ \AA}^{-3}$	0.24/-0.34
Flack parameter	.

**Table 2.** Fractional atomic coordinates ( $\times 10^4$ ) and equivalent isotropic displacement parameters ( $\text{\AA}^2 \times 10^3$ ) for **104**.  $U_{\text{eq}}$  is defined as 1/3 of the trace of the orthogonalised  $U_{\text{ij}}$  tensor.

## 4 Curriculum Vitae

Ludwig Konrad Alois Pils

### *Personal Data*

<b>Date of Birth</b>	<b>07/26/1985</b>
<b>Marital status</b>	Unmarried
<b>Nationality</b>	German
<b>Email</b>	ludwig.pils@ur.de

### *Education*

<b>02/2014 – Current</b>	Postdoctoral fellow in the group of <i>Prof. A. J. Wilson</i> (School of Chemistry, University of Leeds, UK)
<b>10/2010 – 01/2014</b>	PhD thesis in the group of <i>Prof. O. Reiser</i> (University of Regensburg, Germany)
<b>09/2011 – 10/2011</b>	Research stay with <i>Prof. R. M. Ortuño</i> (Universitat Autònoma de Barcelona, Spain)
<b>09/2010</b>	Master of Science in Chemistry
<b>01/2010 – 09/2010</b>	Master of Science thesis in the research groups of <i>Prof. O. Reiser</i> and <i>Prof. T. A. Martinek / Prof. F. Fülöp</i> (University of Szeged, Hungary)
<b>11/2008 – 12/2009</b>	Internship in the research group of <i>Prof. O. Reiser</i>
<b>10/2008 – 09/2009</b>	Advanced studies in Organic Chemistry
<b>09/2008</b>	Bachelor of Science in Chemistry
<b>03/2008 – 06/2008</b>	Bachelor of Science thesis in the research group of <i>Prof. O. Reiser</i>
<b>10/2005 – 09/2010</b>	Studies in Chemistry, University of Regensburg, Germany
<b>09/1996 – 07/2005</b>	Abitur ( <i>A-levels</i> ) Gymnasium (secondary school) Kelheim, Germany, <i>High school Certificate equivalent.</i>

**Referees**

Prof. Dr. Oliver Reiser  
Institut für Organische Chemie  
Universität Regensburg, Universitätsstr. 31  
D-93053 Regensburg, Germany  
[oliver.reiser@ur.de](mailto:oliver.reiser@ur.de)

Prof. Dr. Tamás A. Martinek  
Institute of Pharmaceutical Chemistry  
University of Szeged, Eötvös u. 6  
H-6720 Szeged, Hungary  
[martinek@pharm.u-szeged.hu](mailto:martinek@pharm.u-szeged.hu)

Prof. Dr. Rosa M. Ortuno Mingarro  
Department of Chemistry  
Universitat Autònoma de Barcelona  
Cerdanyola del Vallès  
E-08193 Barcelona, Spain  
[rosa.ortuno@uab.es](mailto:rosa.ortuno@uab.es)

**List of publications**

1. **Enantioselective cyclopropanation of *N*-Boc-pyrrole – synthesis of homo- $\beta$ -proline.**  
L. Pilsl, T. Ertl, O. Reiser, *manuscript in preparation*.
2. **Larvae of the parasitoid wasp *Ampulex compressa* sanitize their host, the American cockroach, with a blend of antimicrobials.**  
G. Herzner, A. Schlecht, V. Dollhofer, C. Parzefall, K. Harrar, A. Kreuzer, L. Pilsl, J. Ruther, *Proc. Natl. Acad. Sci. U. S. A.* **2013**, *110*, 1369-1374.
3. **Unique  $\alpha,\beta$ - and  $\alpha,\alpha,\beta,\beta$ -peptide foldamers based on cis- $\beta$ -aminocyclopentanecarboxylic acid.**  
Ł. Berlicki, L. Pilsl, E. Wéber, I. M. Mándity, C. Cabrele, T. A. Martinek, F. Fülöp, O. Reiser, *Angew. Chem.* **2012**, *124*, 2251-2255; *Angew. Chem. Int. Ed.* **2012**, *51*, 2208-2212.
4.  **$\alpha/\beta$ -Peptide foldamers: state of the art.**  
L. Pilsl, O. Reiser, *Amino Acids* **2011**, *41*, 709-718.

## Conferences

**Foldamers: From Design to Protein Recognition** – European Institute of Chemistry and Biology, Bordeaux-Pessac (France), January 25-28, 2010. “*Synthesis of new unnatural amino acids for foldamers and neuropeptide Y (NPY) analogues as selective ligands for NPY receptors*” (poster).

**Peptidkémia** – Balatonszemes (Hungary), May 26-28, 2010.

**Foldamers: Design, Synthesis and Applications** – Alma Mater Studiorum Università di Bologna (Italy), October 6-8, 2010. “*De Novo design of new  $\alpha,\alpha,\beta,\beta$ -peptide foldamers*” (oral communication, 20 min).

**10th German Peptide Symposium** – Freie Universität Berlin (Germany), March 7-10, 2011. “*De Novo design of new  $\alpha,\alpha,\beta,\beta$ -peptide foldamers*” (short lecture 3 min + poster).

**Foldamers: Synthesis and Structure of Functional Materials** – Casa de Convalescència, Barcelona (Spain), April 7-9, 2011. “*De Novo design of  $\alpha/\beta$ -peptide foldamers*” (short lecture 5 min + poster).

**4th EuCheMS Chemistry Congress** – Prague Congress Centre, Prague (Czech Republic), August 26-30, 2012. “*Copper-catalyzed enantioselective cyclopropanations of heterocyclic compounds using diazoacetates*” (poster).

**Foldamers: Synthesis and Structure of Functional Materials** – Universität Regensburg (Germany), August 30 – September , 2012. “*Asymmetric cyclopropanation reactions of heterocyclic substrates – toward  $\beta$ -aminocyclopropanecarboxylic acids ( $\beta$ -ACCs)*” (short lecture 5 min + poster).

**11th German Peptide Symposium** – Technische Universität München (Germany), March 18-21, 2013. “*De Novo design of secondary structure motifs from mixed  $\alpha/\beta$ -peptide foldamers*” (short lecture 3 min + poster).

**Paris 2013 Symposium on Foldamers** – Les Cordeliers Paris (France), April 10-12, 2013. “*Foldamers under pressure*” (poster).

**15th International Conference ‘Heterocycles in Bio-organic Chemistry’** – Latvian Institute of Organic Synthesis Riga (Latvia), May 27-30, 2013. “*Asymmetric cyclopropanation of heterocycles*” (oral communication 15 min + poster).

## **H Acknowledgments – Danksagung**

*Herzlich bedanken möchte ich mich bei:*

- Prof. Oliver Reiser für die interessante Themenstellung, die beständige Unterstützung während der gesamten Arbeit und die Ermöglichung meines Auslandsaufenthalts.
- Prof. Rosa M. Ortuño, Dr. Ona Illa, sowie allen Mitarbeitern für die freundliche Aufnahme in den Arbeitskreis in Barcelona.
- Prof. Dr. Dr. Hans-Robert Kalbitzer und Prof. Dr. Werner Kremer für die Messungen der NMR Spektren unter Hochdruck.
- Prof. Dr. Roland Winter für die Messungen der FTIR Spektren unter Hochdruck und Hilfe bei deren Auswertung.
- Dr. Peter Kreitmeier, Dr. Sabine Amslinger und besonders Prof. Dr. Kirsten Zeitler für fachkundige Diskussionen und Hilfestellungen bei Problemen jeglicher Art.
- Allen Mitarbeitern der Zentralen Analytik der Universität Regensburg für sämtliche Messungen und bereitwillige Hilfestellung bei Problemen.
- Georg Adolin, Klaus Döring, Helena Konkel, besonders Roxanne Harteis für synthetische Hilfestellungen, sowie unseren Sekretärinnen Antje Weigert, Young Rothermund und Hedwig Ohli für die stete Hilfsbereitschaft bei Problemen jedweder Art.
- Meinen Freunden und Laborkollegen Daniel Rackl, Andreas Okun, Dr. Klaus Harrar und Dr. Markus Hager, sowie Dr. Gang Xu, Dr. Yudha S. Salprima, Dr. Woraluk Mansawat für die stets lockere und angenehme Atmosphäre im Labor.
- Dr. Georgiy Kachkovskyi für seine Ratschläge, Hilfestellungen und interessante Diskussionen über Chemie und andere Dinge.
- Matthias Knorn für die Bereitstellung der Isonitrile und Oxazoline.
- Karin, Andi, Tom, Jimmy, Corina, Soraia, Francesca (Franzi), Roland, Paul, Christian, Matze, Hana Seo, Sudipta, Sebastian, Michl, Julian, Pietro, Mattia Marchini, Marco

Durini, Quirin, Andreas Bergmann, sowie allen aktuellen und ehemaligen Mitgliedern des Arbeitskreises.

- Thomas Ertl für seine Freundschaft, gute Laune, morgendlichen Kaffee, Ertl Bräu und alle Unterstützung und Hilfe während der letzten Jahre.
- Soraia Fernandes für ihre Freundschaft, Offenheit, Lebensfreude und die Einführung in portugiesische Kultur (*bacalhau, fado* usw.)
- Martin (Jimmy) Hofmann, Corina Eichenseer, Daniel Rackl und Thomas Ertl für das Korrekturlesen dieser Arbeit.
- Meinen ehemaligen Bachelorstudenten und Forschungspraktikanten Max Halder, Thomas Hausler, Yannick Mousli, Marco Peteranderl, Thomas Ertl und Uwe Faltermeier für synthetische Unterstützung und anregende Diskussionen.
- Meinen Freunden Agnes und Klaus, Judith und Markus, Hans, Flo, Alex, Ignaz, Micha und Wolle, Heike und Patrick, Matt und Caro, Julia und Carlos, Michel und Anni.
- Meinen Kollegen und Freunden aus Barcelona Jimena, Fernando, Alessandro, Raquel, Enric, Marta und Adaris.
- Prof. Tamás A. Martinek, Dr. István M. Mándity und Dr. Edit Wéber für die freundliche Aufnahme an den Arbeitskreis in Szeged, die langjährige Freundschaft, sowie Hilfestellungen jeglicher Art.
- Meinen Eltern, Anna und Ludwig, sowie Lisa, den 'Passauern' und meiner gesamten Familie für die ganze Unterstützung im Laufe der Jahre.
- Meiner Verlobten Berni für die unermessliche Hilfe, Unterstützung und Geduld in den letzten Jahren.

# **Declaration**

Herewith I declare that I have made this existing work single-handed. I have only used the stated utilities.

Regensburg, February 14, 2014

Ludwig K. A. Pilsl
