## Abstract

Polycystic kidney disease (PKD) leads to continuous decline of renal function by growth of renal cysts. Enhanced proliferation and transepithelial chloride secretion through cystic fibrosis transmembrane conductance regulator (CFTR) and  $\text{Ca}^{2+}$ -activated TMEM16A  $\text{Cl}^-$  channels is thought to cause an increase in cyst volume. Recent work shows the pro-proliferative role of the  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  channel TMEM16A (anoctamin 1), and demonstrates the essential contribution of TMEM16A to CFTR-dependent  $\text{Cl}^-$  secretion. The present data demonstrate an increase in intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ) signals and  $\text{Cl}^-$  secretion by TMEM16A, in renal collecting duct principle cells from dog (MDCK) and mouse (M1) as well as primary tubular epithelial cells from PKD1<sup>-/-</sup> knockout mice. M1 organoids proliferated, increased expression of TMEM16A, and secreted  $\text{Cl}^-$  upon knockdown of endogenous polycystin 1 or 2 (PKD1,2), by retroviral transfection with shPKD1 and shPKD2, respectively. Knockdown of PKD1 or PKD2 increased basal intracellular  $\text{Ca}^{2+}$  levels and enhanced purinergic  $\text{Ca}^{2+}$  release from endoplasmic reticulum. In contrast, ryanodine receptors were found not to be expressed in mouse renal epithelial cells and caffeine had no effects on  $[\text{Ca}^{2+}]_i$ .  $\text{Ca}^{2+}$  signals, proliferation, and  $\text{Cl}^-$  secretion were largely reduced by knockdown or blockade of TMEM16A. TMEM16A may be therefore important for enhanced  $\text{Ca}^{2+}$  release from  $\text{IP}_3$ -sensitive  $\text{Ca}^{2+}$  stores in polycystic kidney disease.

## Key messages

- ADPKD leads to continuous decline of renal function by growth of renal cysts.
- Knockdown of PKD1 or PKD2 increases TMEM16A expression.
- TMEM16A enhanced intracellular  $\text{Ca}^{2+}$  signals,  $\text{Cl}^-$  secretion, and proliferation.
- TMEM16A contributes to cyst growth in ADPKD.

## Introduction

Frequent autosomal dominant polycystic kidney disease (ADPKD) accounts for 5–10% of end-stage renal disease [1]. ADPKD is characterized by continuous cyst enlargement over time, leading to compression of adjacent healthy parenchyma [2]. ADPKD is caused by mutations in PKD1 (polycystin 1) or PKD2 (polycystin 2), but the underlying complex molecular events leading to continuous cyst growth are still poorly understood [3]. In normal renal epithelial cells, PKD1 and PKD2 appear to be located in the primary cilium, a single antenna-like protrusion of the plasma membrane, where they form a complex of receptor and  $\text{Ca}^{2+}$  influx channel [4].  $\text{Ca}^{2+}$  ions are more concentrated within the primary cilium compared to

the cytoplasm; however,  $\text{Ca}^{2+}$  signals generated within the cilium may occur independent of cytoplasmic  $\text{Ca}^{2+}$  signaling [5]. Loss of the primary cilium or loss of PKD1/PKD2 function leads to relocation of the polycystins to plasma membrane and endoplasmic reticulum, with the consequence of disturbed intracellular  $\text{Ca}^{2+}$  signaling [6].

We reported earlier an upregulation of the  $\text{Ca}^{2+}$  activated chloride channel TMEM16A (anoctamin 1) in polycystic kidney disease. TMEM16A enables calcium-activated chloride secretion that supports expansion of renal cysts and probably proliferation of the cyst-forming epithelium [7]. Remarkably, primary cilia present in terminally differentiated naïve cells or in non-proliferating cells in culture, contain TMEM16A as well as the paralogous proteins TMEM16F and TMEM16K [8–10]. Loss of expression of TMEM16A was shown to compromise ciliary genesis and decreased length of the primary cilium and of motile cilia [8, 11, 12].

In the presence of TMEM16A, basal and agonist-induced  $\text{Ca}^{2+}$  levels are increased [13, 14]. TMEM16A was shown to couple to inositol 1,4,5-trisphosphate ( $\text{IP}_3$ ) receptors [13, 14] and different TRP  $\text{Ca}^{2+}$  influx channels [15]. TMEM16A enhances ER  $\text{Ca}^{2+}$  store release by tethering the ER to the membrane localized receptor signaling complex. As a result, transmembrane signaling, fluid secretion, or general cellular properties like proliferation, migration, or volume regulation are affected. We examined in the present study whether TMEM16A contributes to disturbed  $\text{Ca}^{2+}$  signaling observed in ADPKD. We further asked whether TMEM16A-related changes in  $\text{Ca}^{2+}$  signaling affect proliferation and fluid secretion. We found upregulation of TMEM16A with the loss of PKD1 or PKD2 expression in M1 collecting duct cells. In M1 cells, TMEM16A supported  $\text{Ca}^{2+}$  store release, cell proliferation, and fluid secretion and thereby contributed to cyst growth.

## Results

### TMEM16A augments fluid secretion by increase in intracellular $\text{Ca}^{2+}$

We demonstrated earlier the impact of TMEM16A on fluid secretion and cyst growth in a MDCK cyst model and in embryonic kidney cultures [7]. MDCK cells derived from dog principle cells exist as a MDCK-C7 clone expressing TMEM16A, and as a MDCK-M2 clone, lacking expression of TMEM16A (Fig. 1a). The  $\text{Ca}^{2+}$  sensor Fura2 showed a remarkable increase in intracellular  $\text{Ca}^{2+}$  when MDCK-C7 cells were stimulated with the purinergic agonists ATP or UTP (Fig. 1b–d). In contrast, MDCK-M2 cells lacking expression of TMEM16A showed a much reduced  $\text{Ca}^{2+}$  response upon purinergic stimulation. In TMEM16A-expressing MDCK-C7 cells, a pronounced  $\text{Cl}^-$  secretion was activated by ATP/UTP, which was potently inhibited by small

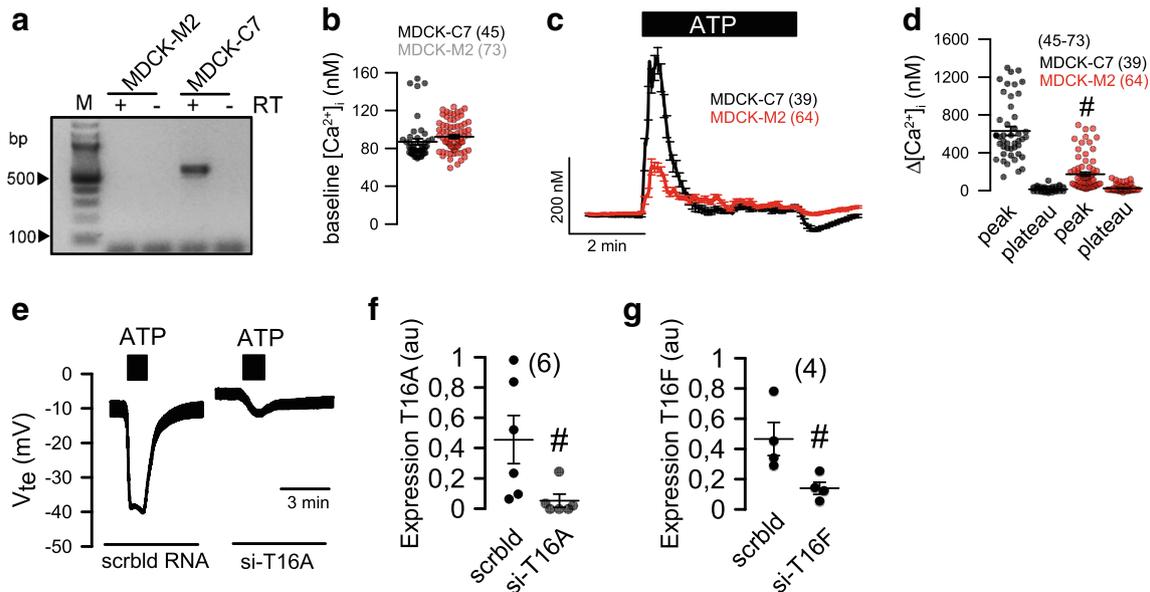

interfering RNA (siRNA)-knockout of TMEM16A (Fig. 1e) [7]. In contrast,  $\text{Cl}^-$  secretion is largely reduced in MDCK-M2 cells, as reported earlier [9]. Moreover, because siRNA-knockdown of TMEM16F did not affect  $\text{Ca}^{2+}$  activated  $\text{Cl}^-$  currents, the data suggest that TMEM16A is the  $\text{Ca}^{2+}$ -activated  $\text{Cl}^-$  channel in MDCK-C7 cells, similar to other tissues (Fig. 1f, g) [9]. TMEM16A was found to be expressed in plasma membrane and primary cilium of MDCK and naïve renal tubular epithelial cells [8, 10] (Fig. 2a).  $\text{Ca}^{2+}$  changes in primary cilium and near the plasma membrane were measured using 5-HT6-G-GECO1 (kindly provided by Prof. Takamari Inoue, Johns Hopkins University, Baltimore, USA; Fig. 2b). A  $\text{Ca}^{2+}$  rise in both cilium and near plasma membrane was detected upon purinergic stimulation with ATP or UTP (Fig. 2c–e). Importantly, peak increase in  $[\text{Ca}^{2+}]_i$  (store release) was similar in plasma membrane and cilium also in the absence of extracellular  $\text{Ca}^{2+}$  (Fig. 2f, g). Purinergic  $\text{Ca}^{2+}$  rise was larger in the primary cilium than close to the plasma membrane, but otherwise qualitatively similar. It was attenuated in MDCK-M2 cells lacking expression of TMEM16A (Fig. 2h, i). Moreover, overexpression of TMEM16A in MDCK-M2 increased the ATP-induced  $\text{Ca}^{2+}$  signal in both cilium and plasma membrane. These results are in line with the previously reported role of TMEM16 proteins in  $\text{Ca}^{2+}$  signaling [14].

### Loss of PKD1 or PKD2 induces $\text{Cl}^-$ secretion in M1 renal organoids

We further examined the role of TMEM16A and other PKD-associated proteins for cyst growth, cell proliferation, and  $\text{Ca}^{2+}$  signaling using a 3D culture model. To that end, M1 mouse collecting duct cells were analyzed for expression of the relevant proteins polycystin (PKD1, PKD2), TMEM16A, TMEM16F, CFTR, NKCC1, and  $\alpha\beta\gamma$ -ENaC (Fig. 3a). Cells were grown in a collagen/Matrigel matrix and readily formed spherical renal organoids (Fig. 3b, c). The cells appeared highly differentiated and produced primary cilia (Fig. 3d, e). Importantly, M1 renal organoids do not seem to secrete fluid, because the NKCC1 inhibitor bumetanide did not interfere with the formation and growth of the organoid (Fig. 3f, g). However, organoids expressed epithelial  $\text{Na}^+$  channels and increased their volume when grown in amiloride (not shown). Knockdown of PKD1 or PKD2 increased the organoid volume, and this increase in volume was inhibited by bumetanide, indicating activation of ion secretion upon knockdown of polycystins and induction of a cystic phenotype (Figs. 3f, g and 4c).

### Enhanced secretion and proliferation in PKD requires TMEM16A

A hallmark of renal cysts is the upregulation of proliferation [16]. TMEM16A is well known to cause cell proliferation,  $\text{Cl}^-$  secretion and proliferation. The proliferation marker Ki-67

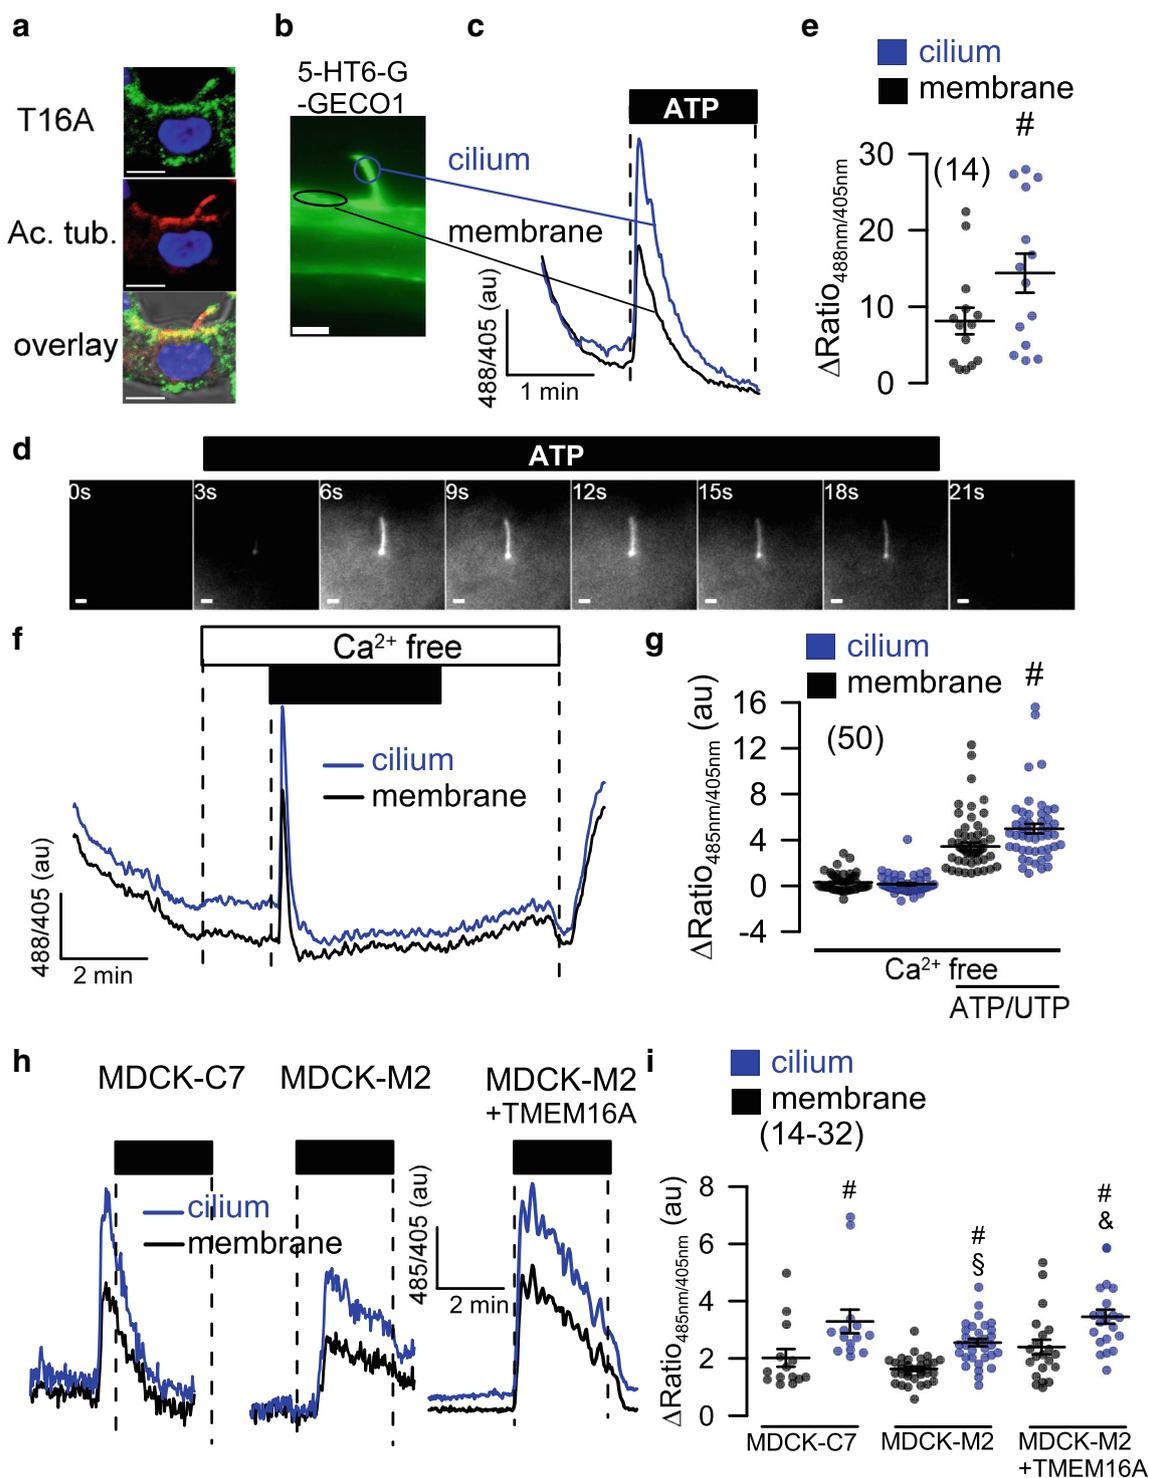

**Fig. 1** TMEM16A augments Ca<sup>2+</sup> signaling and ion transport in MDCK cells. **a** RT-PCR indicating expression of TMEM16A in MDCK-C7 cells but not in MDCK-M2 cells. **b** Summary of basal Ca<sup>2+</sup> levels in MDCK-C7 and MDCK-M2 cells. **c, d** Assessment of intracellular Ca<sup>2+</sup> using the Ca<sup>2+</sup> sensor Fura2. demonstrated a strong upregulation of proliferation of M1 renal organoids upon knockdown of PKD1 or PKD2 (Fig. 4a). The effect of short hairpin RNA (shRNA)-PKD1 and shRNA-PKD2 was analyzed by Western blotting/densitometry and indicated a knockdown by 61% and 92%, respectively. In addition, significant suppression of messenger RNA (mRNA) for PKD1 and PKD2 was demonstrated by semi-quantitative RT-PCR (Fig. 4b, c). Attenuation of expression of PKD1 or PKD2 and consecutive rise in cell proliferation was paralleled by a strong increase in TMEM16A expression (Fig. 4a, green staining). The increase in cell proliferation and enhanced TMEM16A-dependent secretion further enhanced the volume of M1 organoids (Fig. 4a, d). In contrast, organoid volume was significantly reduced in the presence of benzbramarone CaCCinhAO1, and Ani9, potent inhibitors of TMEM16A (Fig. 4d, Fig. S1). Moreover, both inhibitors blocked proliferation of M1 cells as measured in proliferation assays (Fig. 4e). M1 cells were grown as 2D cultures on permeable supports. Knockdown of PKD1 or PKD2 caused enhanced Cl<sup>-</sup> secretion when stimulated by the Ca<sup>2+</sup>-dependent purinergic agonist ATP (Fig. 5a, c). Also, cAMP-dependent transport activated by IBMX and forskolin (IF) was augmented with knockdown of PKD1 or PKD2 (Fig. 5b, d). The data suggest that both Ca<sup>2+</sup>-activated TMEM16A and cAMP-dependent CFTR Cl<sup>-</sup> channels contribute to renal cyst development. Co-staining of TMEM16A (green) and calreticulin (red) indicate upregulation of TMEM16A in plasma membrane and cytosol with knockdown of PKD1 or PKD2, while colocalization of TMEM16A with calreticulin was not observed (Fig. 5e, f).

### Disturbed Ca<sup>2+</sup> signaling in PKD relies on TMEM16A

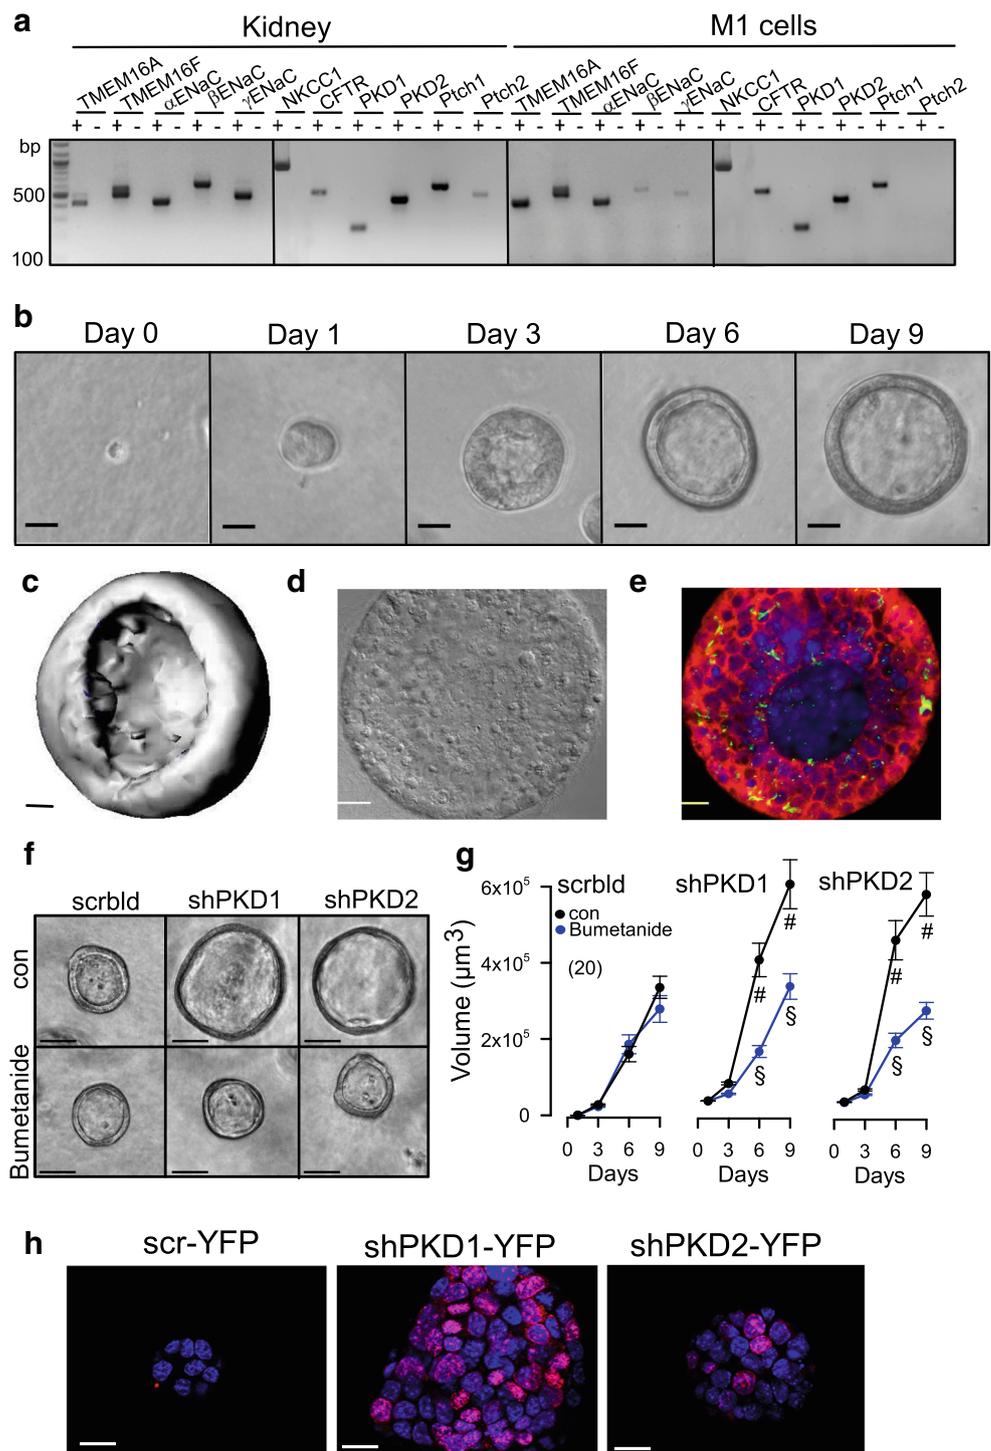

Abrogated Ca<sup>2+</sup> signaling in ADPKD has been intensely examined, but controversial results have been reported [6]. We reported a role of TMEM16A in Ca<sup>2+</sup> signaling, i.e., enhanced agonist-induced Ca<sup>2+</sup>-store release by TMEM16A [14]. Here, we examined the role of TMEM16A for ER Ca<sup>2+</sup>-store release through IP<sub>3</sub>R and ryanodine receptors (RyR) upon knockdown of PKD1 and PKD2. shRNA-knockdown of PKD1 or PKD2 upregulated expression of TMEM16A (Fig. 6a). Densitometric analysis indicates an upregulation of TMEM16A by 1.6 (shPKD1)- and 1.8 (shPKD)-fold. Knockdown of PKD1 or PKD2 enhanced basal [Ca<sup>2+</sup>]<sub>i</sub> and augmented ATP-induced store release (Fig. 6b–d). The enhanced Ca<sup>2+</sup> signals observed in the absence of PKD1 or PKD2 required the presence of TMEM16A, as both basal Ca<sup>2+</sup> levels and ATP-induced store release were strongly attenuated by siRNA-knockdown of TMEM16A, which was 49 ± 3.8% (n = 5) (Fig. 6a, c–f). Successful knockdown of TMEM16A was further validated by real-time RT-PCR and was 91 ± 8.5% (n = 3). Expression of TMEM16A is found in primary cilium and plasma membrane of polarized grown renal epithelial cells (Fig. 6g, upper panel). Similar to M1-organoids, also M1-monolayers increase expression of TMEM16A upon knockout of PKD1 or PKD2 (Fig. 6g, lower panel). Using the ER Ca<sup>2+</sup> sensor ER-LAR-GECO1, we found higher basal ER Ca<sup>2+</sup> levels and enhanced ATP-induced Ca<sup>2+</sup> release in cells lacking expression of PKD1 or PKD2 (Fig. 6h–j). In contrast, knockdown of TMEM16A (Fig. 6a) strongly reduced store filling and ATP-induced Ca<sup>2+</sup>-release (Fig. 6k).

**Fig. 2** Role of TMEM16A in plasma membrane and primary cilium of MDCK cells. **a** TMEM16A (green), acetylated tubulin (red), and overlay showing expression of TMEM16A in primary cilium and plasma membrane of a naïve renal epithelial cell. **b** Ca<sup>2+</sup> sensor 5-HT6-G-GECO1 expressed in the primary cilium and near plasma membrane allowing measurement of Ca<sup>2+</sup> in both compartments. **c–e** Original recordings and summary of Ca<sup>2+</sup> signals elicited by stimulation with ATP or UTP (both 100 μM) in primary cilium and near plasma membrane.

### Upregulated TMEM16A causes enhanced ER store release and store refill in ADPKD

Ryanodine receptors were claimed to have a role in flow-induced  $\text{Ca}^{2+}$  increase in mouse kidney [3]. However, the activator of RyR, caffeine, did not increase intracellular  $\text{Ca}^{2+}$ . Moreover, we did not detect expression of RyR1-3 in

primary tubular epithelial cells from wild-type or PKD1 $^{-/-}$  knockout animals, or M1 collecting duct cells (Fig. 7a, b). In contrast, signals for RyR1–3 were clearly present in skeletal muscle, heart muscle, and brain, respectively (not shown). Lack of PKD1 or PKD2 increased store emptying induced by inhibition of SERCA with cyclopiazonic acid (CPA). Moreover, store-operated  $\text{Ca}^{2+}$  entry (SOCE) was also

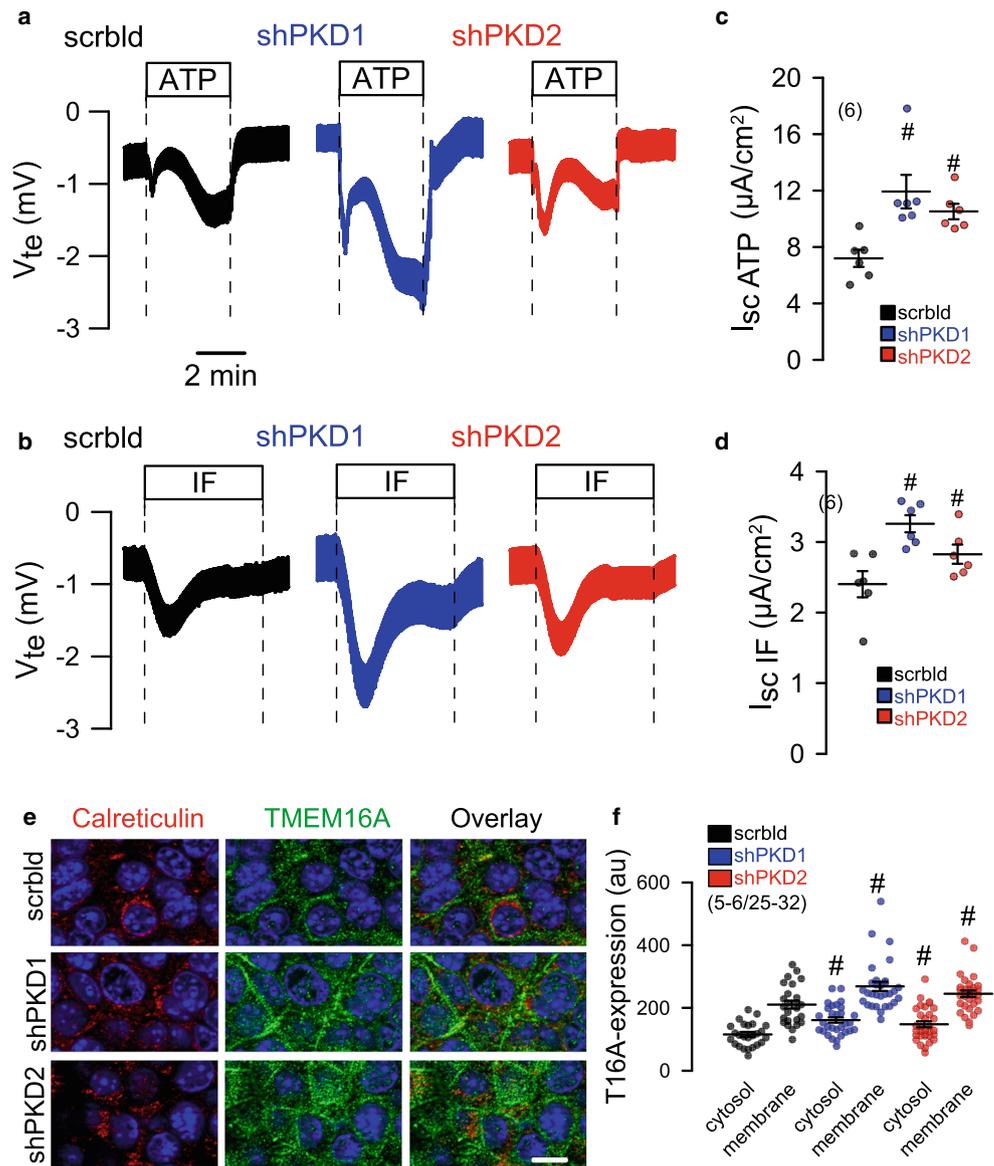

**Fig. 4** Increased expression of TMEM16A, proliferation and organoid growth by knockdown of PKD1 or PKD2. **a** Knockdown of both PKD1 or PKD2 induced cell proliferation (Ki-67 staining; red), enhanced expression of TMEM16A (green) and growth of M1 organoids. **b**, **c** Western blot and quantification of mRNA by semi-quantitative RT-PCR indicates significant knockdown of PKD1 and PKD2 by small hairpin (sh) RNA. enhanced by knockdown of PKD1/PKD2 (Fig. 7c, d). Enhanced store release and enhanced SOCE was strongly reduced in the absence of TMEM16A (Fig. 7e, f). Moreover, the

inhibitor of transient receptor potential (TRP) channels SK&F96365 and the ORAI inhibitor YM58483 inhibited enhanced  $\text{Ca}^{2+}$  entry in PKD1/PKD2 knockout cells and

Enhanced  $\text{Cl}^-$  secretion by luminal stimulation with ATP (100  $\mu\text{M}$ ) or IF (100  $\mu\text{M}$  IBMX and 2  $\mu\text{M}$  forskolin) upon shRNA-knockdown of PKD1 or PKD2. **b, d** Summaries for calculated equivalent basal short-circuit currents ( $I_{\text{sc}}$ ) and  $I_{\text{sc}}$  activated by ATP and forskolin/IBMX, respectively. **e, f** Co-staining of TMEM16A (green) and calreticulin. Knockdown of PKD1 or PKD2 upregulated TMEM16A in plasma membrane and cytosol. No colocalization with calreticulin was observed. Bar = 20  $\mu\text{m}$ . Mean  $\pm$  SEM (number of organoids measured). #Significant difference when compared scrambled ( $p < 0.05$ ; ANOVA)

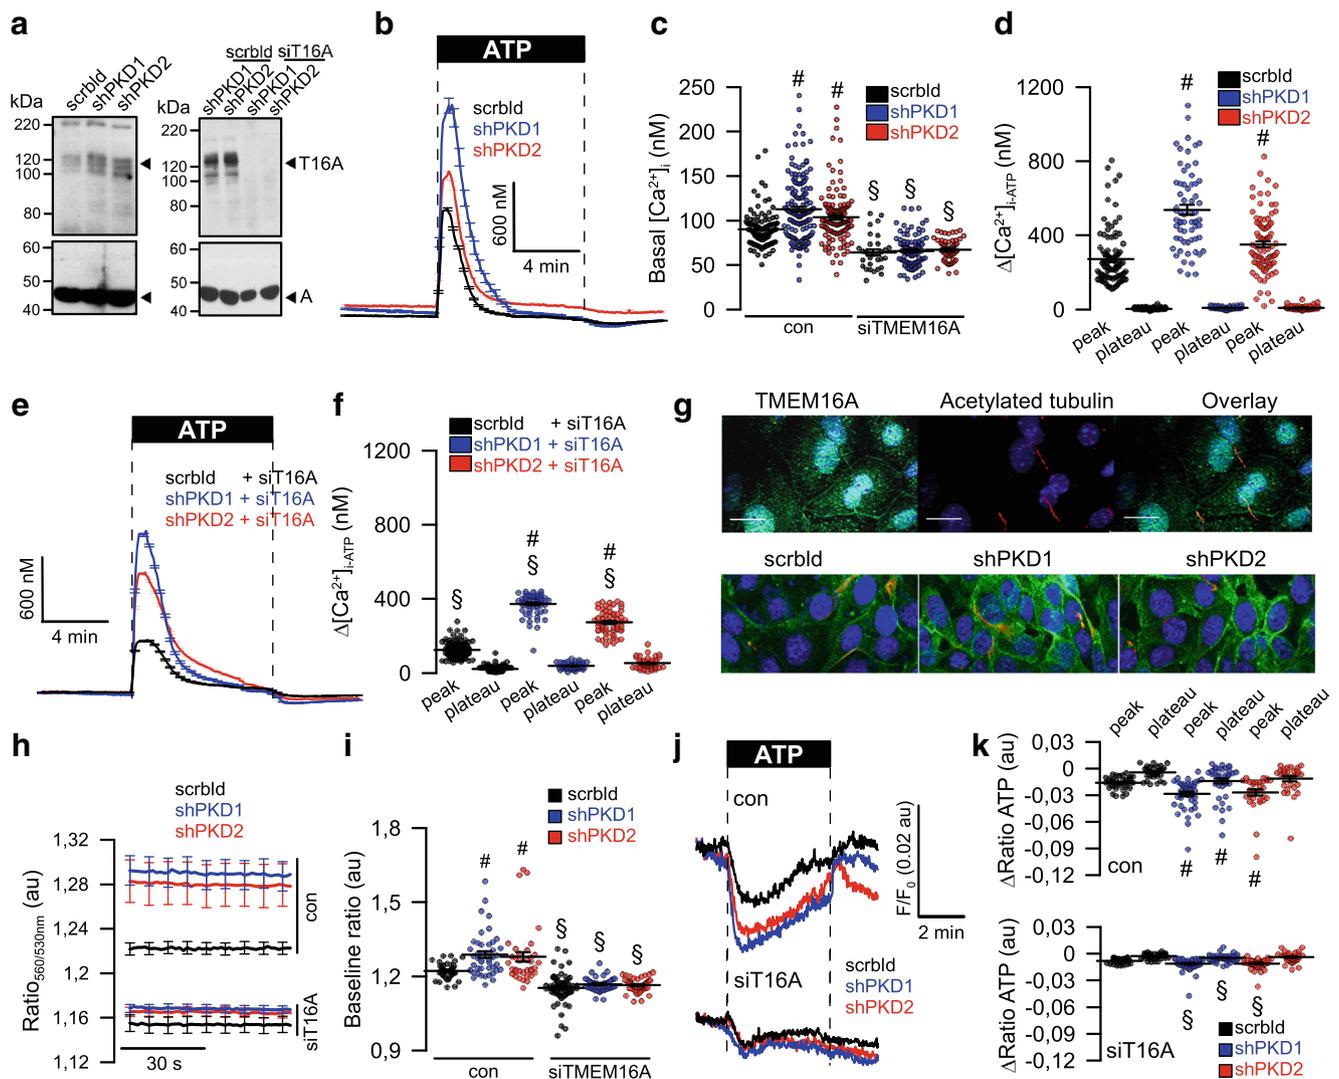

abolished enhanced CPA-induced store release (Fig. 7g–j). Finally, to confirm the present results in M1 cells, we compared primary renal tubular epithelial cells from PKD<sup>+/+</sup> and PKD1<sup>-/-</sup> mice. We found enhanced ATP-induced Ca<sup>2+</sup> store release, with a consecutive enhancement of store-operated Ca<sup>2+</sup> influx (SOCE) in cells from PKD<sup>-/-</sup> animals, almost identical to the results obtained in M1 cells (Fig. 8). Taken together, the present data demonstrate augmented Ca<sup>2+</sup> signals in the absence of either PKD1 or PKD2. These enhanced Ca<sup>2+</sup> signals are caused by upregulation of TMEM16A  $\text{Cl}^-$  channels.

### Discussion

Aberrant intracellular Ca<sup>2+</sup> signaling enhanced cell proliferation and fluid secretion are essential factors that drive growth

of renal cysts [2]. Disturbed flow sensing and mechanical activation of Ca<sup>2+</sup> influx into primary cilia were proposed as major mechanisms in ADPKD, a concept that has been questioned recently [17]. In the present paper, we found ATP-induced Ca<sup>2+</sup> increase in both the primary cilium as well as in the cytosol near the plasma membrane of MDCK cells (Fig. 2). Although ciliary Ca<sup>2+</sup> increase by ATP was larger, the responses in the cilium and the cytoplasm were similar. Both PKD1 and PKD2 are required for cellular trafficking and proper colocalization in the primary cilium of differentiated renal epithelial cells [3, 18]. Mutations or lack of expression of PKD2 may lead to compromised trafficking and accumulation of PKD1 in the ER, while defective or missing PKD1, loss of the primary cilium, or overexpression of PKD2 leads to enhanced density of PKD2 in the apical membrane and in the ER membrane [19]. Apart from localization within the primary

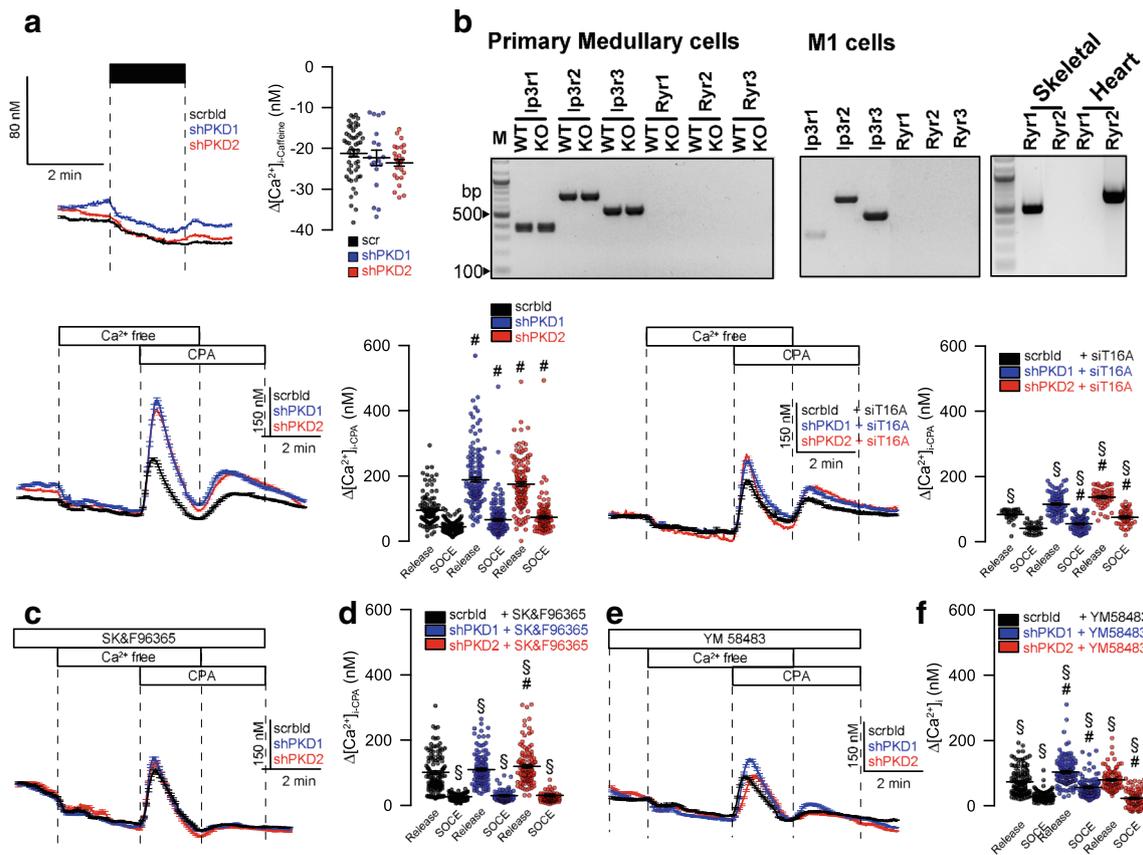

**Fig. 6** Upregulation of TMEM16A is essential for enhanced  $\text{Ca}^{2+}$  signaling upon knockdown of PKD1 and PKD2. **a** Left: Western blot indicating upregulation of TMEM16A by shRNA-knockdown of PKD1 or PKD2. Blots were performed  $n=3$  times. Protein loading was not normalized among the lanes. Densitometric analysis indicates an upregulation of TMEM16A by 1.6- (shPKD1) and 1.8 (shPKD2)-fold. Right: siRNA-knockdown of TMEM16A upregulated by shRNA-knockdown of PKD1 or PKD2. Blots were performed in replicates. siRNA-knockdown of TMEM16A protein was  $49 \pm 3.8\%$  ( $n=5$ ; western blotting) and  $91 \pm 8.5\%$  ( $n=3$ , real-time PCR). **b–d** Original recordings and summaries of basal  $\text{Ca}^{2+}$  and ATP (100  $\mu\text{M}$ )-induced  $\text{Ca}^{2+}$  increase

(Fura2) in control cells (scrblid), and cells with a knockdown of PKD1 or PKD2, respectively. **e, f** Original recordings and summaries of ATP-induced  $\text{Ca}^{2+}$  increase in cells lacking expression of TMEM16A (siT16A). **g** Expression of TMEM16A in M1 control cells (scrblid) and cells lacking expression of PKD1 or PKD2. **h–j** Original recordings and summaries of the effect of ATP on ER  $\text{Ca}^{2+}$  levels in control cells and cells lacking expression of PKD1 or PKD2. **k** Attenuated ATP-induced  $\text{Ca}^{2+}$  release after knockdown of TMEM16A. cilium, both PKD1 and PKD2 have been detected at different subcellular locations (reviewed in [6]). In fact, most studies reported intracellular ER-localized PKD2. However, many studies have been performed in cultured cells under non-differentiated conditions. Moreover, it is notoriously difficult to obtain specific immunocytochemistry signals for the both proteins.

Inhibition of the  $\text{IP}_3$  receptors by PKD1, with attenuation of  $\text{Ca}^{2+}$  release from  $\text{IP}_3$ -sensitive stores has been reported

earlier [20]. Accordingly, receptor-mediated  $\text{Ca}^{2+}$  release will be enhanced with the loss of PKD1, as also observed in the present study. After proteolytic cleavage, a PKD1 fragment has been proposed to interact with the ER  $\text{Ca}^{2+}$ -sensor STIM1 to inhibit store-operated calcium entry [21]. Lack of PKD1 therefore is likely to augment store-operated calcium entry, which is also shown here (Fig. 7). Enhanced  $\text{Ca}^{2+}$  entry was blocked by the inhibitor of receptor-mediated  $\text{Ca}^{2+}$  entry SK&F96365, and by the inhibitor of store-operated Orail

**Fig. 7** TMEM16A is essential for enhanced  $\text{Ca}^{2+}$  store release by knockdown of PKD1 and PKD2. **a, b** Lack of effects of caffeine on intracellular  $\text{Ca}^{2+}$  and lack of expression of RyR1–3 in mouse primary renal medullary and M1 collecting duct cells. **c, d** CPA (10  $\mu\text{M}$ ) induced store release in the presence or absence PKD1/PKD2. **e, f** CPA-induced store release was strongly attenuated by siRNA-knockdown of

TMEM16A. **g–j** Original recordings and summaries of CPA-induced  $\text{Ca}^{2+}$  store release and SOCE in the presence of SK&F96365 and YM58483 (both 5  $\mu\text{M}$ ). $\text{Ca}^{2+}$  influx channels, YM58483 (Fig. 7). Enhanced (and mis-localized) expression of PKD2 in the ER in the absence of PKD1 is likely to operate as a  $\text{Ca}^{2+}$ -activated ER  $\text{Ca}^{2+}$  leakage channel, which will contribute to enhanced  $\text{Ca}^{2+}$  release from IP<sub>3</sub>-sensitive (IP<sub>3</sub>R) stores (Fig. 8). Notably, abnormal  $\text{Ca}^{2+}$  permeability of the ER membrane in ADPKD may account for both change in apoptotic activity and increased proliferation [16].

The present data are in line with the role of TMEM16A for intracellular  $\text{Ca}^{2+}$  signaling, which we reported earlier in cell models and transgenic animals [14]. TMEM16A channels enhance ER- $\text{Ca}^{2+}$  store release by sequestering the ER and IP<sub>3</sub> receptors to  $\text{Ca}^{2+}$  signaling compartments near the plasma membrane. However, in contrast to an earlier report [3], we were unable to detect any contribution of RyR channels in mouse primary renal epithelial cells or M1 cells (Fig. 7i, j).

The role of CFTR-dependent  $\text{Cl}^-$  secretion for growth of renal cysts has been implicated for long. We showed earlier that formation of cysts by principal-like MDCK

cells is due to a synergism between cAMP and  $\text{Ca}^{2+}$ -mediated fluid secretion [22]. The relevance of  $\text{Ca}^{2+}$ -activated TMEM16A  $\text{Cl}^-$  channels became evident through our recent work [7, 23, 24]. Notably, STAT6-dependent transcription is upregulated in ADPKD [25]. Because expression of TMEM16A is also upregulated through activation of STAT6 (and STAT3), this could explain upregulation of TMEM16A in M1 cysts observed in the present study (Fig. 4a). Notably, TMEM16A supports proliferation, cell migration, and development of cancer by recruiting a number of intracellular signaling pathways [26]. Although the contribution of TMEM16A to ADPKD is not yet fully understood, the present data provide evidence for a pronounced impact on the disturbed intracellular  $\text{Ca}^{2+}$  signaling, caused by elimination of PKD1 or PKD2. As a number of potent inhibitors for TMEM16A are already available, TMEM16A may represent a novel drug target in the therapeutic regimen of polycystic kidney disease.

**Fig. 8** Enhanced  $\text{Ca}^{2+}$  signaling in primary renal tubular epithelial cells from PKD $^{-/-}$  mice. **a–c** Original recordings and summaries of basal  $\text{Ca}^{2+}$  and ATP (100  $\mu\text{M}$ ) induced  $\text{Ca}^{2+}$  increase (Fura2) in primary renal epithelial cells isolated from wild type mice (PKD $^{+/+}$ ) and from mice with a renal tubular knockout of PKD1 (PKD $^{+/+}$ -KspCre). **d, e** Original recordings and summaries of  $\text{Ca}^{2+}$  increase induced by inhibition of SERCA with CPA (10  $\mu\text{M}$ ). Store release and store-operated  $\text{Ca}^{2+}$  influx (SOCE) was augmented in PKD $^{-/-}$  cells. Mean  $\pm$  SEM (number of cells measured). #Significant difference when compared to wt ( $p < 0.05$ ; ANOVA)

## Material and methods

**Cells, animals, virus production RT-PCR, complementary DNA (cDNA):** MDCK M2 and C7 cell lines were cultured in DMEM supplemented with 10% fetal bovine serum (FBS). M1 cells were cultured DMEM/F12 medium supplemented with 5% (v/v) fetal bovine serum (FBS), 1% insulin-transferrin-selenium 100x (ITS), and 1% L-glutamine 200 mM (all from Capricorn Scientific GmbH, Ebsdorfergrund, Germany) at 37 °C in a humidified incubator in 5% (v/v)  $\text{CO}_2$ . M1 cells were transduced to downregulate Pkd1 and Pkd2. Mice with a floxed PKD1 allele were generously provided by Prof. Dr. Dorien J.M. Peters (Department of Human Genetics, Leiden University Medical Center, Leiden, The Netherlands) [27]. Experiments were approved by the local Ethics Committee of the Government of Unterfranken/Wuerzburg (AZ: 55.2–2532–2-328). Animals were euthanized between week 8 and 12, medullary tubular epithelial cells were isolated and were kept as primary culture. M1 cells were infected with lentiviral recombinant vectors containing the shRNAs of mouse Pkd1 (5'-GAATATCG GTGGGAGATAT) and Pkd2 (5'-GCATCTTGACCTAC GGCATGA) with YFP $_{1152L}$ , as previously described [28, 29]. Stable transfected M1 cells were maintained in the presence of 5  $\mu\text{g}/\text{ml}$  of Puromycin (Thermo Fisher Scientific, Darmstadt, Germany).

For semi-quantitative RT-PCR total RNA from M1 cells, MDCK cells and murine kidney were isolated using NucleoSpin RNA II columns (Macherey-Nagel, Düren, Germany). Total RNA (1  $\mu\text{g}$  / 50  $\mu\text{l}$  reaction) was reverse-transcribed using random primer (Promega, Mannheim, Germany) and M-MLV Reverse Transcriptase RNase H Minus (Promega, Mannheim, Germany). Each RT-PCR reaction contained sense (0.5  $\mu\text{M}$ ) and antisense primer (0.5  $\mu\text{M}$ ) (Table 1), 0.5  $\mu\text{l}$  cDNA, and GoTaq polymerase (Promega, Mannheim, Germany). After 2 min at 95 °C, cDNA was amplified (30 cycles) for 30 s at 95 °C, 30 s at 57 °C, and 1 min at 72 °C. Real-time PCR of cDNA samples was performed in a LightCycler 480 device (Roche, Basel, Switzerland) using specific, intron-spanning primers (Table 2) and a SYBR® Green mastermix (Takyon, Eurogentec, Belgium). Target gene expression levels were quantified relative to beta-actin expression under consideration of PCR efficiencies calculated on the basis of standard dilution curves. The specificity of PCR amplifications was verified by agarose electrophoresis and melting curve analysis. PCR products were visualized by loading on peqGREEN (Peqlab; Düsseldorf, Germany) containing agarose gels and analyzed using ImageJ.

**Western blotting:** Protein was isolated from cells using a sample buffer containing 25 mM Tris-HCl, 150 mM NaCl, 100 mM dithiothreitol, 5.5% Nonidet P-40, 5% glycerol, 1 mM EDTA, and 1% protease inhibitor mixture (Roche, Mannheim, Germany). Proteins were separated by 7% sodium

dodecyl sulfate (SDS) polyacrylamide gel and transferred to a polyvinylidene difluoride membrane (GE Healthcare Europe GmbH, Munich, Germany) or 4–20% Mini-PROTEAN TGX Stain-Free (Bio-Rad) using a semi-dry transfer unit (Bio-Rad). Membranes were incubated with primary anti-Tmem16a rabbit polyclonal antibody (Davids Biotech, Regensburg, Germany; 1:1000), anti-PKD1 (Polycystin-1 (7E12), Santa Cruz; 1:500) mouse antibody or anti-PKD2 (Polycystin-2 (D-3), Santa Cruz; 1:500) mouse antibody, overnight at 4 °C. Proteins were visualized using horseradish peroxidase-conjugated secondary antibody and ECL detection. Actin was used as a loading control. Equal amounts were loaded on each blot! Total protein on the blots was exactly the same under all conditions. Because the  $\beta$ -actin bands always show similar bands under all conditions and independent of the treatment with shPKD1, shPKD2, or siT16A (Figs. 4b and 6a),

treatments do not change the expression of  $\beta$ -actin and this  $\beta$ -actin can be used as a reference point.

**M1 organoid model:** M1 cells were resuspended as a single-cell suspension in 50/50% Matrigel/type I collagen and transferred into 24-well plates ( $30 \times 10^3$  cells/well, four wells per condition) for 9 days. Medium was changed every 3 days. Every 3 days, 30 random visual fields per well were photographed with an Axiovert 200 microscope (Zeiss, Germany). Cyst area of the lumina (~30–150 cysts per condition and single experimental procedure) was measured with AxioVision (Zeiss, Germany). Cyst volume was then estimated using the formula for the volume of a sphere,  $4/3\pi r^3$ .

**Immunocytochemistry:** M1 cells grown under confluent conditions for 4 days on glass coverslips and M1 organoids grown for 6 days were fixed for 10 min with methanol at  $-20$  °C. Organoids were isolated with ice-cold 5 mM EDTA in PBS and seeded in poly-L-lysine-coated coverslips. After seeding cells were fixed for 10 min with methanol at  $-20$  °C. After washing, cells were permeabilized with 0.5% (v/v, PBS) Triton X-100 for 10 min and blocked with 1% (w/v, PBS) bovine serum albumin for 1 h at room temperature. The cells were incubated overnight with primary antibodies (1:100) against rabbit anti-TMEM16A [30] (Davids Biotechnologie, Regensburg, Germany), rat anti-Ki-67 (DAKO, M7249, Germany), anti-mouse CFTR antibody ACL-006 (Alomone labs, Jerusalem, Israel), or mouse anti-acetylated tubulin (T7451, Sigma-Aldrich, Germany). Binding of the primary antibody was visualized by incubation with

appropriate secondary antibodies conjugated with Alexa Fluor 488 or Alexa Fluor 546 (1:300, Molecular Probes, Invitrogen). Nuclei were stained with Hoe33342 (0.1 g/ml PBS, AppliChem, Darmstadt, Germany). Glass coverslips were mounted on glass slides with fluorescent mounting medium (DakoCytomation, Hamburg, Germany) and examined with an ApoTome Axiovert 200 M fluorescence microscope (Zeiss, Germany).

**Cell proliferation assay:** M1 cells were plated in 96-well plates at a density of  $2 \times 10^3$  cells per well for the time duration as indicated (0, 3, 6, and 9 days). Medium was changed every 3 days. Cells were incubated for 2 h in 100  $\mu$ l of fresh media containing 0.5 mg/ml of the tetrazolium salt MTT. The dark blue formazan product was dissolved with DMSO and measured the absorbance at 595 nm.

**Ussing chamber:** MDCK or M1 cells were grown as polarized monolayers on permeable supports (Millipore MA, Germany) for 8 days. Cells were mounted into a perfused micro-Ussing chamber, and the luminal and basolateral surfaces of the epithelium were perfused continuously with Ringer's solution (mmol/l: NaCl 145;  $\text{KH}_2\text{PO}_4$  0.4;  $\text{K}_2\text{HPO}_4$  1.6; glucose 5;  $\text{MgCl}_2$  1;  $\text{Ca}^{2+}$  gluconate 1.3) at a rate of 5 ml/min (chamber volume 2 ml). Bath solutions were heated to 37 °C, using a water jacket. Experiments were carried out under open-circuit conditions. In addition, 100  $\mu$ M ATP/UTP was added on the apical or basolateral side, or 100  $\mu$ M 3-isobutyl-1-methylxanthine and 2  $\mu$ M Forskolin (I/F) were added on the basolateral side, or 2  $\mu$ M ionomycin was added on the apical side, as indicated in the figure. Data were collected continuously using PowerLab (AD Instruments, Australia). Values for transepithelial voltages ( $V_{te}$ ) were referred to the basolateral side of the epithelium. Transepithelial resistance ( $R_{te}$ ) was determined by applying short (1 s) current pulses ( $\Delta I = 0.5 \mu\text{A}$ ).  $R_{te}$  and equivalent short-circuit currents ( $I_{SC}$ ) were calculated according to Ohm's law ( $R_{te} = \Delta V_{te}/\Delta I$ ,  $I_{SC} = V_{te}/R_{te}$ ).

**Measurement of  $[\text{Ca}^{2+}]_i$ :** Primary cilium and membrane  $\text{Ca}^{2+}$  signals were detected after MDCK M2 and C7 cell were transfected with 5HT6-mCherry-GECO1.0 (5HT6-GECO, Addgene, Cambridge, MA, USA [31]). Cells were grown to confluence in glass coverslips and serum starved for 4–6 days to induce cilium formation. Afterwards, the cells were mounted and perfused in Ringer's solution. The mCherry fluorescence of the indicator was used to localize the  $\text{Ca}^{2+}$  sensor. Therefore, before each experiment, a photo was taken exciting the 5HT6-GECO at 560 nm, and the emission was recorded between  $620 \pm 30$  nm using a CCD-camera (CoolSnap HQ, Visitron Systems, Germany). To measure the ciliary  $\text{Ca}^{2+}$  changes, 5HT6-GECO was excited at 485/405 nm, and the emission was recorded between  $535 \pm 12.5$  nm. The results for  $[\text{Ca}^{2+}]_{\text{cilium}}$  and  $[\text{Ca}^{2+}]_{\text{cyt}}$  were obtained at 485/405 nm changes and given in ratio. Measurement of the global cytosolic  $\text{Ca}^{2+}$  changes was performed as described recently [32]. In brief, cells were loaded with 5  $\mu$ M Fura-2, AM (Molecular Probes) in OptiMEM (Invitrogen)

with 0.02% pluronic (Molecular Probes) for 1 h at RT and 30 min at 37 °C. Fura-2 was excited at 340/380 nm, and the emission was recorded between 470 and 550 nm using a CCD-camera (CoolSnap HQ, Visitron Systems, Germany). Control of experiment, imaging acquisition, and data analysis were done with the software package Meta-Fluor (Universal imaging, USA).  $[\text{Ca}^{2+}]_i$  was calculated from the 340/380 nm fluorescence ratio after background subtraction. The formula used to calculate  $[\text{Ca}^{2+}]_i$  was  $[\text{Ca}^{2+}]_i = Kd \times (R - R_{\min}) / (R_{\max} - R) \times (S_{f2}/S_{b2})$ , where  $R$  is the observed fluorescence ratio. The values  $R_{\max}$  and  $R_{\min}$  (maximum and minimum ratios) and the constant  $S_{f2}/S_{b2}$  (fluorescence of free and  $\text{Ca}^{2+}$ -bound Fura-2 at 380 nm) were calculated using 1  $\mu$ mol/l ionomycin (Calbiochem), 5  $\mu$ mol/l nigericin, 10  $\mu$ mol/l monensin (Sigma), and 5 mmol/l EGTA to equilibrate intracellular and extracellular  $\text{Ca}^{2+}$  in intact Fura-2-loaded cells. The dissociation constant for the Fura-2- $\text{Ca}^{2+}$  complex was taken as 224 nmol/l. ER  $\text{Ca}^{2+}$  signals were detected in  $\text{Ca}^{2+}$  sensor ER-LAR-GECO1 (Addgene, Cambridge, MA, USA [33]), expressing M1 cells. Cells were excited at 560 nm and emission was recorded between  $620 \pm 30$  nm.

**Materials and statistical analysis:** All compounds used were of highest available grade of purity. Data are reported as mean  $\pm$  SEM. Student's  $t$  test for unpaired samples and ANOVA were used for statistical analysis.  $p < 0.05$  was accepted as significant difference. We are grateful to Prof. Dr. Dorien J.M. Peters (Department of Human Genetics, Leiden University Medical Center, Leiden, The Netherlands) for providing us with animals with a floxed PKD1 allele. We acknowledge the support by Ms. Ana Fonseca.

**Acknowledgments** Open Access funding provided by Projekt DEAL. The 5HT6-G-GECO1.0 was kindly provided by Prof. Takanari Inoue at Johns Hopkins University School of Medicine, Baltimore, USA, and was obtained through addgene (Watertown, MA, USA). The number of experiments is provided for each single experiment. Statistical differences between samples were examined using paired and unpaired Student's  $t$  tests, with significance assumed when  $p < 0.05$ , after variance homogeneity of the samples were tested by F-test. Differences between more than two means were tested by using one-way ANOVA with a Bonferroni-Holm multiple comparisons test (post-hoc test) with significance assumed when  $p < 0.05$ .
