**Parts of this work have been published in peer-reviewed open-access journals:**

Biasella F, Plössl K, Karl C, Weber BHF, Friedrich U. (2020). Altered protein function caused by AMD-associated variant rs704 links vitronectin to disease pathology. *Invest Ophthalmol Vis Sci*, 61(14):2. doi: 10.1167/iovs.61.14.2

Biasella F, Strunz T, Kiel C, on behalf of the International AMD Genomics Consortium (IAMDGC), Weber BHF, Friedrich U. (2022). Vitronectin and its interaction with PAI-1 suggests a functional link to vascular changes in AMD pathobiology. *Cells*, 11 (11):1766. doi.org/10.3390/cells11111766

## **Table of Contents**

|   |    |
|---|----|
| Zusammenfassung .....   | 1  |
| Summary .....   | 3  |
| 1. Introduction .....   | 5  |
| 1.1 Age-related Macular Degeneration.....                                       | 5  |
| 1.1.1 The Retina Under Healthy Conditions.....                                  | 5  |
| 1.1.2 The Pathology of AMD.....   | 7  |
| 1.1.2.1 Clinical Findings.....  | 7  |
| 1.1.2.2 Aetiology and Pathobiology .....  | 9  |
| 1.1.2.2.1 Age-related Changes of the Retina .....                               | 10 |
| 1.1.2.2.2 AMD-related Changes of the Retina.....                                | 10 |
| 1.1.3 Treatment and Emerging Therapies in AMD .....                             | 12 |
| 1.2 The Genetics of AMD .....   | 13 |
| 1.2.1 From GWAS-associated Genetic Loci to Causal Susceptibility Variants ..... | 14 |
| 1.2.2 Genetic Variant rs704 and Its Association With AMD.....                   | 16 |
| 1.3 Vitronectin .....   | 17 |
| 1.3.1 Vitronectin Expression, Structure and Processing.....                     | 17 |
| 1.3.2 Functionality of Vitronectin.....   | 19 |
| 1.3.3 Contribution of Vitronectin to AMD Development .....                      | 20 |
| 1.3.4 Effect of rs704 on Vitronectin.....                                       | 21 |
| 1.4 Aim of the Study.....   | 21 |
| 2. Materials .....  | 23 |
| 2.1 Eukaryotic Cell Lines.....  | 23 |
| 2.2 Escherichia (E.) Coli Strains.....  | 23 |
| 2.3 Oligonucleotide Primers and Probes for PCR and Sequencing Reactions.....    | 23 |
| 2.4 Plasmids and Expression Constructs .....                                    | 25 |
| 2.5 Primary Antibodies .....  | 25 |
| 2.6 Secondary Antibodies .....  | 27 |
| 2.7 Enzymes .....   | 27 |

|        |  |    |
|--------|--|----|
| 2.8    | Molecular Weight Standards .....   | 28 |
| 2.9    | Kit Systems .....  | 28 |
| 2.10   | Chemicals .....  | 28 |
| 2.11   | Readymade Solutions/Buffers .....  | 30 |
| 2.12   | Solutions and Buffers .....  | 31 |
| 2.13   | Cell Culture Mediums and Supplements.....                                | 32 |
| 2.14   | Consumables .....  | 33 |
| 2.15   | Devices/Tools.....   | 34 |
| 2.16   | Software.....  | 36 |
| 3.     | Methods .....  | 37 |
| 3.1    | Genomic DNA Isolation and Purification.....                              | 37 |
| 3.2    | RNA Isolation and Purification.....                                      | 37 |
| 3.3    | cDNA Synthesis by Reverse Transcription of Total RNA.....                | 37 |
| 3.4    | Targeted DNA Amplification by Polymerase Chain Reaction (PCR).....       | 38 |
| 3.5    | Agarose Gel Electrophoresis.....   | 38 |
| 3.6    | Purification of PCR Products.....  | 38 |
| 3.7    | Sanger Sequencing.....   | 39 |
| 3.8    | Quantitative Real-time PCR .....   | 39 |
| 3.9    | Generation of Expression Vectors Encoding for PAI-1 .....                | 40 |
| 3.9.1  | Ligation into pGEM®-T Vector .....                                       | 40 |
| 3.9.2  | Heat-shock Transformation of <i>E. coli</i> .....                        | 40 |
| 3.9.3  | Plasmid DNA Purification from <i>E. coli</i> .....                       | 41 |

## **Zusammenfassung**

Die altersabhängige Makuladegeneration (AMD) ist eine häufige Erkrankung der zentralen Netzhaut. Derzeit sind die Pathomechanismen der Krankheit nur unvollständig verstanden, was erfolgreiche therapeutische Strategien zur Bekämpfung der initialen Ereignisse der Krankheit wesentlich erschwert. In den letzten Jahren haben genomweite Assoziationsstudien (GWAS) eine Vielzahl von genetischen Variationen aufgezeigt, die sich auf bestimmte biologische Prozesse auswirken, wie z. B. die Organisation und Funktion der extrazellulären Matrix (ECM), die Komplementaktivierung und den Lipid-/Cholesterinstoffwechsel, die allesamt für die AMD eine wichtige Rolle spielen. Bis heute ist die molekulare und biologische Bedeutung der meisten AMD-assoziierten genetischen Varianten jedoch funktionell nicht geklärt.

In dieser Dissertation wurde eine funktionelle Untersuchung der AMD-assoziierten, nicht-synonymen rs704C>T-Variante im *VTN*-Gen, (ursprünglich reportiert von Fritsche und Kollegen, 2016), durchgeführt. Die rs704C>T-Variante führt zu einer Aminosäuresubstitution T400M im kodierten Vitronectin-Protein, einem zirkulierenden und matrizellulären Protein, das schon früher in die Pathologie der AMD als Schlüsselkomponente und koordinierender Faktor der abnormen extrazellulären Ablagerungen, die für die Krankheit charakteristisch sind, impliziert wurde. Hierzu wurde die nicht AMD-risikoassoziierte Vitronectin-Isoform VTN\_rs704:C und die AMD-risikoassoziierte Isoform VTN\_rs704:T in einer Reihe von *in vitro* Tests verglichen, um die Auswirkungen von rs704 auf die mRNA- und Proteinexpression, die Prozessierung und weitere funktionelle Aspekte von Vitronectin zu überprüfen.

Die Analyse der mRNA-Expression in retinalem Pigmentepithel (RPE), das aus humanen induzierten pluripotenten Stammzellen (hiPSC) differenziert wurde, und in Netzhautgewebe von Spendern, die heterozygot für rs704 waren, zeigte keine Auswirkung von rs704 auf die Transkription der beiden *VTN*-Isoformen. Nach heterologer Expression in humanen embryonalen Nierenzellen (HEK293-EBNA) und kultivierten RPE-Zellen (ARPE-19) wurde für die AMD-assoziierte Isoform VTN\_rs704:T im Vergleich zur nicht AMD-assoziierten Isoform VTN\_rs704:C ein dramatischer Anstieg der Proteinkonzentration und eine reduzierte endoproteolytische Prozessierung festgestellt.

Beide Vitronectin-Isoformen zeigten nach partieller thermischer Denaturierung eine ähnliche Suszeptibilität für den Trypsin-Verdau. Über Blue Native und nicht-reduzierende SDS-PAGE wurde gezeigt, dass beide Vitronectin-Isoformen eine ähnliche Multimerisierung aufweisen.

In Versuchen, welche die Bindung der beiden Vitronectin-Isoformen an Zellen adressierten, zeigte VTN\_rs704:T im Vergleich zu VTN\_rs704:C eine reduzierte Bindefähigkeit an die Zelloberflächen von ARPE-19, hiPSC-RPE und isolierten porcinen RPE-Zellen sowie an Y79-Retinoblastomzellen und humanen Nabelvenen-Endothelzellen (HUVECs).

Beide Isoformen von Vitronectin verstärkten in ähnlicher Weise die Adhäsion von porcinen RPE und ARPE-19 Zellen und führten zu einer Inhibierung des extrazellulären Signal-regulierten Kinase (ERK)-Signalwegs in ARPE-19-Zellen, wobei VTN\_rs704:C hier eine stärkere Wirkung zeigte als VTN\_rs704:T. In HUVECs reduzierten die Vitronectin-Isoformen Adhäsion und Tubulogenese, wohingegen nur die nicht risikoassoziierte Vitronectin-Isoform VTN\_rs704:C die Migration dieser Zellen leicht reduzierte. Kein Einfluss von Vitronectin wurde auf die Regulierung des ERK-Signalwegs in HUVECs verzeichnet. Zudem zeigten beide Vitronectin-Isoformen Auswirkungen auf Autophagie und Zellviabilität von HUVECs und ARPE-19 Zellen.

Nach heterologer Vitronectin-Expression in ARPE-19 Zellen verbesserten die Vitronectin-Isoformen die extrazelluläre Ablagerung und das Clustering der integralen ECM-Komponenten Fibronectin, Elastin und Kollagen, aber nicht von Laminin. Darüber führten beide Vitronectin-Isoformen zu einer verstärkten extrazellulären Ablagerung des angiogenen Faktors VEGF und der Komplementkomponenten C9 und CFH, hatten aber keinen Effekt auf die extrazelluläre Ablagerung des Gewebsinhibitors der Metalloproteinasen-3 (TIMP3). Interessanterweise zeigte die risikoassoziierte AMD-Isoform VTN\_rs704:T dabei eine stärkere Wirkung als die nicht risikoassoziierte Isoform VTN\_rs704:C.

Schließlich wurde die Interaktion der Vitronectin-Isoformen mit dem Vitronectin-Bindungspartner Plasminogen-Aktivator-Inhibitoren (PAI-1), einem in der AMD-Pathologie involvierten Angiogenese-Regulator, untersucht. In Co-Präzipitationsexperimenten zeigte AMD-assoziiertes VTN\_rs704:T eine stärkere Bindung an PAI-1 als nicht-AMD-assoziiertes VTN\_rs704:C, wohingegen in Enzymaktivitätstests beide Isoformen die PAI-1-Aktivität auf vergleichbare Weise stabilisierten. Die Exposition von ARPE-19 Zellen und HUVECs mit VTN\_rs704:C und VTN\_rs704:T erhöhte in ähnlicher Weise die Expression und ECM-Ablagerung von PAI-1.

Zusammengefasst wird durch die Ergebnisse der Arbeit der Beitrag von Vitronectin zur Pathogenese der AMD unterstützt. Darüber hinaus werden neue biologische Wege aufgezeigt, über die dieses Protein die pathologischen Prozesse, die zu dieser schweren Krankheit führen, beeinflussen könnte.

## Summary

Age-related macular degeneration (AMD) is a frequent disorder of the central retina. So far, the pathomechanisms of the disease are incompletely understood, precluding successful therapeutic strategies to address initiating events of the disease. In recent years, genome-wide association studies (GWAS) implicated a plethora of genetic variation affecting specific biological pathways, like extracellular matrix (ECM) organization and function, complement activation and lipid/cholesterol metabolism, as determinants of AMD. Still to date, for most genetic variants associated with AMD the molecular and biological significance remains to be functionally defined.

In this doctoral thesis, a functional investigation of the AMD-associated, non-synonymous rs704C>T variant within the *VTN* gene, originally reported by Fritsche and colleagues (2016), was conducted. This work aimed to explore the pathological significance of the amino acid substitution (T400M) resulting from rs704 in the encoded vitronectin, a circulatory and matricellular protein implicated previously in the pathology of AMD as a key component and coordinating factor of the abnormal extracellular deposits characteristic for the disease. To this end, the non-AMD risk-associated vitronectin isoform VTN\_rs704:C and the AMD risk-associated VTN\_rs704:T isoform were compared in a number of *in vitro* assays to assess the effects of rs704 on mRNA and protein expression, processing and functional aspects of vitronectin.

First, risk and non-risk associated *VTN* mRNA expression in human-induced pluripotent stem cells (hiPSC)-derived retinal pigment epithelium (RPE) and in retinal tissues from donors heterozygous for rs704 revealed no difference between the two *VTN* alleles. In turn, after heterologous expression in human embryonic kidney (HEK293-EBNA) and cultured RPE (ARPE-19) cells a dramatic increase in protein concentration and reduced endoproteolytic processing was found for the AMD risk-associated VTN\_rs704:T isoform compared to the non-AMD risk-associated VTN\_rs704:C isoform.

Second, after partial thermal denaturation both isoforms of vitronectin revealed similar susceptibility to trypsin digestion. Likewise, vitronectin isoforms exhibited an analogous multimerization, as demonstrated by Blue Native and non-reducing SDS-PAGE.

Third, in cell-binding assays, VTN\_rs704:T relative to VTN\_rs704:C showed a reduced ability to bind to the cell surfaces of ARPE-19, hiPSC-RPE and isolated porcine RPE cells, as well as to Y79 retinoblastoma cells and human umbilical vein endothelial cells (HUVECs). Both isoforms of vitronectin similarly increased the adhesion of porcine-derived RPE and ARPE-19 cells. Furthermore, the two isoforms of vitronectin inhibited extracellular signal-regulated kinase (ERK) signalling in ARPE-19 cells, with VTN\_rs704:C showing a greater effect than VTN\_rs704:T. In HUVECs, vitronectin isoforms reduced adhesion and tubulogenesis, while only the non-risk VTN\_rs704:C isoform slightly reduced migration. The analysis revealed no

effect of vitronectin on the regulation of ERK signalling in HUVECs. Both isoforms of vitronectin failed to show any effect on autophagy and cell viability in HUVECs and ARPE-19 cells.

Fourth, after heterologous vitronectin expression in ARPE-19 cells, vitronectin isoforms increased the deposition and clustering of the integral ECM components fibronectin, elastin, and collagen, but not laminin. Furthermore, both isoforms increased the extracellular deposition of the angiogenic factor VEGF and the complement components C9 and CFH but had no effect on the deposition of the tissue inhibitor of metalloproteinase 3 (TIMP3). Interestingly, AMD risk-associated isoform VTN\_rs704:T showed a stronger effect than non-risk-associated VTN\_rs704:C.

Finally, the interaction of vitronectin isoforms with vitronectin binding partner plasminogen activator inhibitor 1 (PAI-1), an angiogenic regulator implicated in AMD pathology, was investigated. In co-precipitation experiments, AMD-associated VTN\_rs704:T showed a stronger binding to PAI-1 than non-AMD-associated VTN\_rs704:C, while in enzyme activity assays both isoforms similarly maintained PAI-1 activity. Exposure of ARPE-19 cells and HUVECs to VTN\_rs704:C and VTN\_rs704:T similarly increased expression and ECM deposition of PAI-1.

Taken together, the results of the thesis confirm and strengthen the contribution of vitronectin to the pathogenesis of AMD and suggest new biological pathways through which this protein might influence the pathological events leading to this devastating disease.

## 1. Introduction

### 1.1 Age-related Macular Degeneration

Age-related macular degeneration (AMD) is a neurodegenerative disorder of the retina, with pathological changes mostly pronounced in the central part termed the macula<sup>1</sup>. Emerging in a spectrum of clinical phenotypes, AMD is the leading cause of severe vision loss in individuals over 60 years of age in the developed world, accounting for 6-9% of legal blindness globally<sup>1,2</sup>. In the European population, the disease shows a pooled annual incidence of 1.4 per 1,000 people (95% confidence interval [CI] 0.8-2.6)<sup>3</sup>, and it has been estimated that 3.9-4.8 million people in Europe will be severely affected by AMD by 2040<sup>2</sup>. Three main elements are generally accepted as risk factors for AMD including increasing age, environmental factors (in particular smoking), and genetic predisposition<sup>4-7</sup>. The interplay between those factors defines AMD as a member of the so-called complex diseases. However, although several etiological possibilities have been formulated, AMD aetiology is far from complete, and much remains elusive about the pathophysiological events that culminate in the disease and how these are affected by genetic and environmental risk factors.

#### 1.1.1 The Retina Under Healthy Conditions

In fundoscopic examination, a healthy retina appears orange-red in colour with a highly pigmented round spot in the macular centre, which has no visible blood vessels. The macula is located laterally and slightly below the optic disc, which can be distinguished as a pale pink region with sharp margins in which all retinal vessels converge<sup>8</sup> (**Figure 1A**). A vertical section through the healthy retina depicts a sophisticated multi-layered architecture (**Figure 1B**), in which different cell types work closely together to maintain retinal homeostasis and process visual information<sup>9</sup>. The neurosensory retina comprises specialised neurons interconnected by synapses and glial cells (Müller cells, astroglia and microglia), which support the structure and homeostasis of the retina<sup>10</sup>. Among neuronal cells, photoreceptors are responsible for the conversion of light into electrical stimuli (visual phototransduction)<sup>11</sup>. Two types of photoreceptors can be distinguished: rods, which specialise in processing dim light and contribute to black and white vision (scotopic vision), and cones, which are responsible for fine resolution and bright colour vision (photopic vision)<sup>12</sup>. The photoreceptor axons communicate with bipolar cells, which transmit signals from the photoreceptors to the retinal ganglion cells, whose axons meet in the optic nerve. The latter conveys the signal to the cerebral cortex. Laterally interconnected neurons, including horizontal cells and amacrine cells, modulate this flow of information<sup>13</sup>. On the outer side, photoreceptor cell bodies extend into a stack of membranous discs (outer segments) filled with rhodopsin, a pigment-containing protein that acts as a light receptor and drives phototransduction<sup>11,14,15</sup>. Supported

by the interphotoreceptor matrix<sup>16</sup>, the outer segments of the photoreceptors are enclosed by microvillous structures of the underlying retinal pigment epithelium (RPE)<sup>13</sup>.

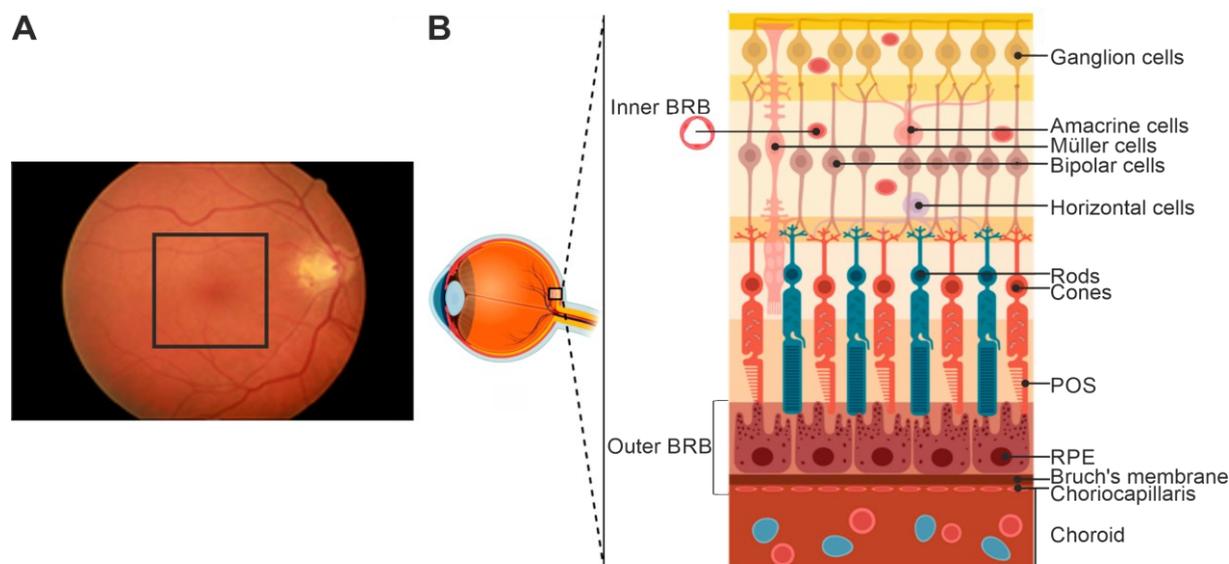

RPE cells are densely packed, single-layered polarised epithelial cells. The apical microvillus of the RPE phagocytoses the outer segments of shed photoreceptors. This essential function ensures the maintenance of a relatively constant outer segment length, which is required for proper photoreceptor function<sup>17-19</sup>. Furthermore, the RPE plays a key role in both the regeneration and storage of retinoids, precursors of the visual pigment rhodopsin<sup>20,21</sup>. The cytoplasm of RPE cells abounds in pigment granules, including melanin, which absorbs the excess light from the photoreceptors and thus has the function of protecting the neuroretina from phototoxicity. Pigmentation of the RPE is also essential for focusing clear images onto the retina<sup>19,22</sup>. To maintain its own survival and the homeostasis of neural and vascular tissue in the retina, the RPE produces growth factors, including vascular endothelial growth factor (VEGF)<sup>23</sup>, which promotes cell viability and regulates retinal vascular permeability and angiogenesis<sup>24,25</sup>. Laterally, RPE cells are connected by tight junctions<sup>26</sup>. This makes this layer act as a physical barrier limiting the transepithelial transport of ions, fluids, and metabolites to selective transport proteins within the apical and basal plasma membranes<sup>27,28</sup>.

The RPE basal lamina is rich in collagen IV (non-fibrillar), fibronectin and laminin, and participates in the formation of Bruch's membrane, a 2-4 µm thick extracellular matrix (ECM)<sup>29</sup>. The remainder of Bruch's membrane consists of two structural collagen layers (inner and outer) rich in type I and III (fibrillar) collagen, which embrace the Bruch's membrane central layer mainly composed of elastin<sup>29</sup>. The choriocapillaris basement membrane, a labyrinth of thin-walled, fenestrated vessels forming the underlying choroid also is part of Bruch's membrane<sup>29</sup>. The function of Bruch's membrane is primarily that of a molecular sieve that regulates the diffusion of biomolecules between the choroid and the RPE. In addition, it provides physical support for RPE cell adhesion, also limiting the migration of choroidal and retinal cells<sup>29,30</sup>.

Together with the RPE and Bruch's membrane, the endothelium of the choriocapillaris form the outer blood retinal barrier<sup>31,32</sup>, which play a major role in rod and cone photoreceptor integrity. The choroidal circulation supplies oxygen and nutrients to the outer portion of the retina simultaneously removing metabolic waste products. In contrast to the outer retina, the inner retinal layers are mainly supplied and cleared by the retinal vasculature. The complex tight junctions of retinal capillary endothelial cells contribute to the formation of the inner blood retinal barrier<sup>33,34</sup>.

In the macula, the retina is adapted for high acuity vision: The exceptionally high density of cone photoreceptors in the centre of the macular region (fovea) enables high-resolution vision<sup>35</sup>. Furthermore, RPE cells are denser, taller, and more pigmented than in the

periphery<sup>36,37</sup>. The extremely high metabolic demand associated with photoreceptor activity at a density above average make this region more vulnerable to oxidative stress, inflammatory events, and degenerative processes<sup>35</sup>.

**Figure 1: Overview of the healthy human retina.**

## 1.1.2 The Pathology of AMD

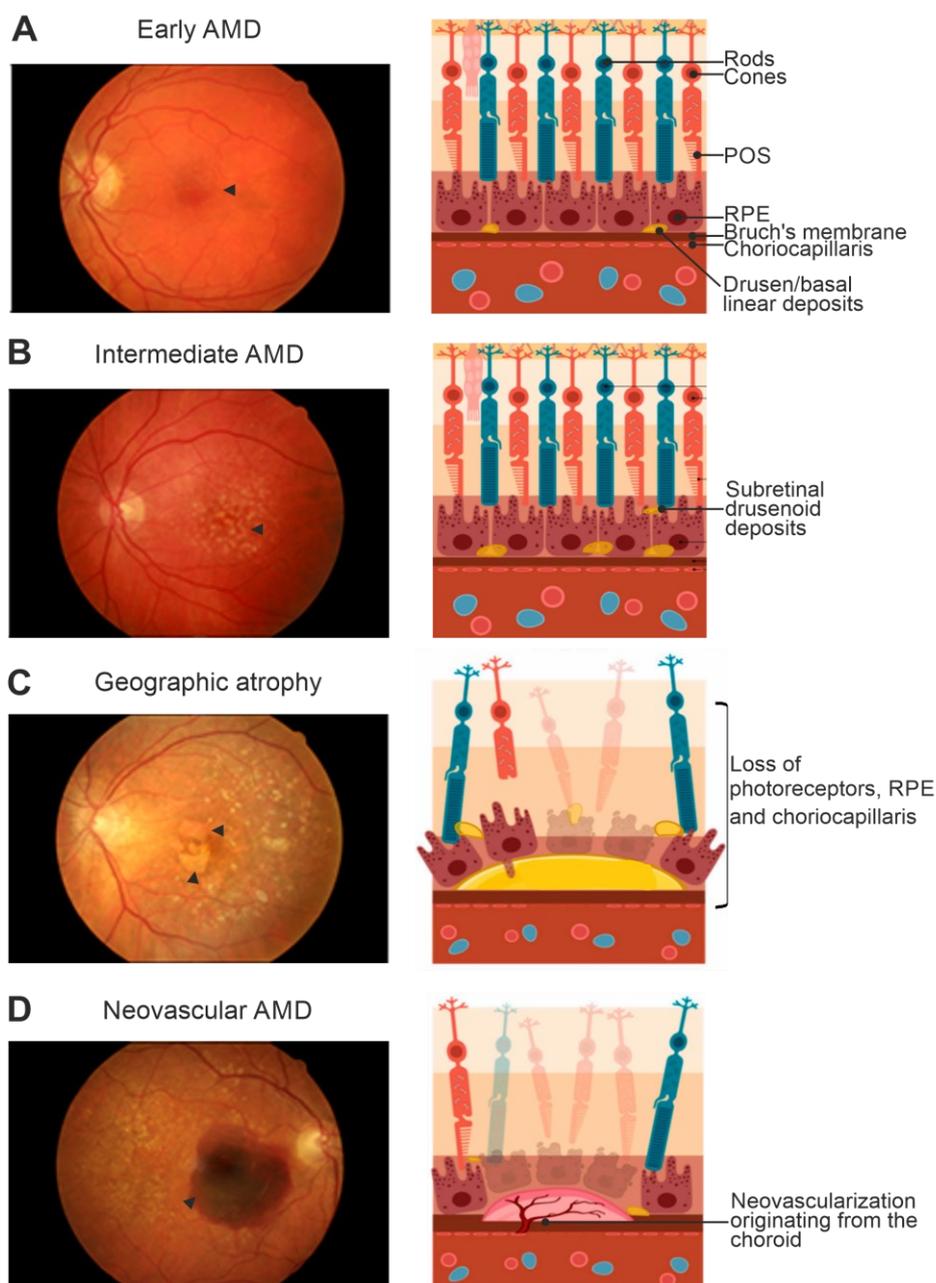

### 1.1.2.1 Clinical Findings

The first clinical manifestation of AMD is the appearance of abnormal extracellular deposits in the macula (known as drusen). On ophthalmoscopy, drusen appear as focal yellow polymorphic spots (**Figure 2**)<sup>1</sup>. Size and number of drusen are indicative of AMD initiation and stage: While the formation of small drusen (< 63  $\mu\text{m}$  in diameter) manifests with ageing but does not represent a clinically relevant risk for developing AMD, medium-sized drusen ( $\geq 63$  and  $\leq 125$   $\mu\text{m}$  in diameter) are associated with early AMD (**Figure 2A**) and large drusen (> 125  $\mu\text{m}$  in diameter), often associated with RPE pigment abnormalities, are considered a sign of intermediate AMD (**Figure 2B**)<sup>39</sup>. Immunohistochemical and proteomic studies have shown that drusen are mainly located between the basal membrane of the RPE and Bruch's membrane and contain a variety of proteins (e.g. circulating serum proteins, immunoglobulins, complement components, amyloid), different lipids (membrane phospholipids, cholesterol, neutral lipids), glycosaminoglycans and hydroxyapatite<sup>40-43</sup>. Furthermore, the appearance of basal laminar deposits (composed mainly of fibrous long-spacing collagen type VI and amorphous material) between the RPE and its basal lamina,

and linear deposits (composed mainly of lipoproteins and membranous material) in the inner collagenous zone of Bruch's membrane, is among the pathological changes seen in early AMD<sup>44-48</sup>. In addition to sub-RPE deposits, the formation of subretinal drusenoid deposits (SDD) between the apical processes of the RPE and the photoreceptors was observed in many patients, representing a risk factor for AMD progression independent of drusen<sup>48-51</sup>. The growth of subretinal deposits becomes more rapid in late-stage forms of AMD<sup>52</sup>.

Two clinically distinct late-stage forms of AMD are described: Atrophic or "dry" AMD is characterised by geographic atrophy (GA-AMD), which reveals circumscribed macular areas in which RPE abnormalities become more pronounced and manifest as foci of hypopigmentation and/or hyperpigmentation, and atrophy. This is accompanied by loss of photoreceptors and of the underlying choriocapillaris membrane (**Figure 2C**). Furthermore, GA-AMD is associated with Bruch's membrane thickening, secondary to deposition of basal laminar and basal linear deposits, and scotoma<sup>45,53</sup>. The progression and enlargement of GA-AMD within the foveal region typically results in a precipitous decline in visual function<sup>54</sup>. The neovascular form of AMD (NV-AMD) is characterised by the abnormal growth of new blood vessels within the macula (**Figure 2D**) and comprises three subtypes. Type 1 is characterised by the growth of vessels initially from the choriocapillaris into and within the sub-RPE space. In type 2 (commonly called choroidal neovascularisation, CNV), neovascular events originate from the choroid and cross Bruch's membrane and the RPE monolayer and proliferate into the sub-retinal space. Finally, neovascularisation originates from the retinal vasculature in type 3<sup>55</sup>. Typically, AMD-associated newly formed vessels are fragile and prone to leakage<sup>56</sup>. Consequently, exudative events including haemorrhage and fluid formation accompany the progression of exudative or "wet" NV-AMD, leading to diffuse cell loss, RPE or retinal detachment, retinal fibrosis and/or subsequent disciform scarring. Metamorphopsia (perception of distorted images) and vision loss appear very rapidly<sup>57,58</sup>. Non-exudative forms of NV-AMD characterised by the presence of new vessels in macular tissue without signs of exudation have also been reported and represent important predictor of exudative complications in NV-AMD<sup>59</sup>.

AMD evolution from early to advanced stages varies from one patient to another<sup>60,61</sup>, however, the reasons behind this variability have not been clarified so far. Of note, GA-AMD and NV-AMD are not necessarily mutually exclusive and can occur simultaneously in the same eye<sup>62</sup>. Also, GA is considered a relevant risk factor for the development of NV-AMD<sup>63</sup>.

**Figure 2: Retinal pathology associated with AMD subtypes.**

(A) Early AMD with medium-sized drusen (black arrowheads in the fundus photograph). (B) Intermediate AMD with non-confluent large drusen and subretinal drusenoid deposits. (C) Geographic atrophy, extensive confluent drusen along the vascular arcades, growing subretinal drusenoid deposits and marked area of cellular atrophy (black arrowheads in fundus photograph). (D) Neovascular AMD, abnormal growth of blood vessels from the choroid plexus invading the overlying retinal layers and causing subretinal haemorrhage (black arrowheads in fundus photograph). Fundus photograph modified from <https://www.luxotticalearning.com.au/pages/luxottica-new-advances-in-the-imaging-and-management-of-age-related-macular-degeneration> (accessed on 20 May 2022); illustration of retinal layers modified from Jensen et al., 2020<sup>38</sup>.

### 1.1.2.2 Aetiology and Pathobiology

The molecular mechanisms that initiate the early formation of AMD-associated deposits and/or lead to progression of the disease in its more advanced stages are not fully understood. However, environmental conditions such as ageing and oxidative stress that accumulate in the eye over time have been implicated in the pathogenesis of AMD<sup>64,65</sup>.

#### 1.1.2.2.1 Age-related Changes of the Retina

The accumulation of metabolic debris and drusen may result from age-dependent changes in the RPE, which has long been suspected to be the primary site of pathology in AMD<sup>66</sup>. As a result of cumulative age-related oxidative damage, RPE cells decrease in concentration, probably due to increased apoptosis<sup>67,68</sup>. In aged RPE cells, reduced lysosomal capacity, impaired autophagy, and altered degradation of the photoreceptor outer segments result in the accumulation of intracellular metabolic debris, including non-degradable lipofuscin<sup>69-71</sup>. By reducing the pigment-free cytoplasmic space, the high lipofuscin content impairs cytoplasmic function of the RPE<sup>72</sup>, e.g., phagolysosomal degradation of photoreceptor phospholipids<sup>73,74</sup>. In addition, the accumulation of lipofuscin and lipids, which are continuously exposed to light, enhance the production of reactive oxygen species (ROS)<sup>75-77</sup>. Defects then follow in oxidative stress-sensitive organelles, such as RPE mitochondria, eventually impacting cellular energy production and ultimately RPE function<sup>78,79</sup>. Oxidative damage and cellular senescence cause RPE cells to adopt a senescence-associated secretory phenotype, which involves the secretion of proinflammatory cytokines, chemokines, and growth factors such as VEGF<sup>80-83</sup>. Abnormal secretion of ECM components by dysfunctional RPE cells and deposition of cytoplasmic material in Bruch's membrane contribute to the age-associated impairment of Bruch's membrane<sup>84,85</sup>. Filamentous membrane debris, glycosaminoglycans, heparan sulphate, cholesterol and calcium phosphate increase their concentration in Bruch's membrane in adulthood, contributing to its thickening<sup>30,86,87</sup>. Furthermore, advanced glycation end products (AGEs) and fat accumulate in this layer<sup>30</sup>. This, together with the increase in collagen density and cross-linking in Bruch's membrane inner and outer collagen layers<sup>88,89</sup>, participates in the reduction of the hydraulic conductivity of Bruch's membrane observed with advancing age<sup>30,90</sup>. Age-dependent changes in Bruch's membrane may also be related to an imbalanced regulation of matrix metalloproteinases (MMPs) and their tissue inhibitors (TIMPs), which play an essential role in the turnover of matrix components (including collagen, elastin, gelatin, matrix glycoproteins and proteoglycans)<sup>85</sup>. Finally, it has been reported that age-dependent changes in the choriocapillaris also play a causal role in the thickening of Bruch's membrane during ageing<sup>64</sup>: Senescence-associated stiffening of choroidal endothelial cells, reduction in choriocapillaris density and lumen diameter lead to a decrease in choroidal blood flow and loss of choriocapillaris cleaning function<sup>88,91,92</sup>. The observed changes in the RPE-Bruch's membrane-choroid complex contribute to chronic low-grade inflammation in the ageing retina<sup>93</sup>.

#### 1.1.2.2.2 AMD-related Changes of the Retina

The age-related processes in the retina coincide with those associated with AMD, although not every aged individual develops AMD<sup>94</sup>. The fact that 33% of the proteins derived from

drusen of AMD donors were not observed in drusen of healthy donors<sup>41</sup> appears to indicate that additional mechanisms may be involved in AMD pathology. Furthermore, while only small drusen (hard drusen) are formed during ageing, large drusen (soft drusen/basal linear deposits) appear during AMD, suggesting that typical debris clearance processes deteriorate over time but at an accelerated rate in AMD development<sup>94</sup>.

Inherited genetic variation together with environment/lifestyle factors (e.g., cigarette smoking, obesity, hypertension) are thought to exacerbate and/or accelerate age-dependent changes and increase the risk of AMD<sup>7</sup>. For example, Bruch's membrane changes, particularly thickening, may worsen disease processes in AMD by a pathological alteration of ECM turnover due to an imbalanced secretion of proteins such as tissue inhibitor of metalloproteinase 3 (TIMP3) and activated MMP-2 and -9 in AMD<sup>95,96</sup>. Such alterations are likely dependent on individual genetic variability<sup>4,97,98</sup>. Also, an aggravated response to oxidative stress appeared in AMD compared to normal ageing, as indicated by significantly elevated oxidative stress markers (including malondialdehyde, protein carbonyl and 8-hydroxy-29-deoxyguanosine) and decreased antioxidant capacity in the serum of AMD patients compared to controls<sup>99,100</sup>. This, in turn, may lead to a culmination of age-related ultrastructural changes in RPE: When cultured on an extracellular substrate like that of AMD, primary RPE cells manifested altered ECM turnover, deposit formation, and complement activation<sup>101</sup>. Furthermore, RPE cells from AMD specimens showed a more pronounced mitochondrial dysfunction than age-matched controls<sup>102</sup>, the extent of which is thought to be determined by genetic variability of mitochondrial and nuclear DNA repair enzymes<sup>103,104</sup>. In addition, RPE cells from AMD donors showed increased accumulation of lipid droplets and glycogen particles, as well as impaired autophagy function<sup>105</sup>. The increased oxidative stress in RPE cells might lead to increased secretion of growth factors such as VEGF, which may amplify normal age-associated changes and promote retinovascular complications in AMD<sup>106,107</sup>. In line with this, an increased concentration of VEGF has also been measured in the ocular fluid and serum of AMD patients<sup>108,109</sup>.

Choroidal density and diameter decrease with age in healthy human eyes; however, these changes appeared more pronounced in eyes with AMD near regions of basal laminar deposits, GA or disciform scars<sup>88</sup>. This, together with a notably reduced choroidal blood flow as seen in patients with AMD<sup>110-112</sup>, would be sufficient, according to the vascular theory of AMD<sup>113</sup>, to initiate RPE dysfunction, accumulation of metabolic debris and drusen formation. Moreover, the decreased choroidal perfusion may lead to ischaemic/hypoxic damage and increased oxidative stress, which could signal the initiation of abnormal choroidal neovascularisation<sup>113,114</sup>. Inevitably, the inflammatory processes that begin in ageing become increasingly active in AMD and include complement and glial activation, as well as macrophage infiltration<sup>115,116</sup>. Increased activation of these pathways results in an increased

pro-inflammatory response that includes the generation of membrane attack complexes (MACs) mediating cell lysis, the release of chemokines to attract inflammatory cells to the site of damage and increased choroidal endothelial permeability to promote the overflow of infiltrating leukocytes <sup>117</sup>. In recent years, genetic association studies have identified polymorphisms in genes encoding complement factors as being associated with AMD and suggested a role for complement dysregulation in disease pathogenesis <sup>118,119</sup>. In line with this, serum concentrations of a number of complement components were higher in AMD patients. Furthermore, in contrast to age-matched control eyes, AMD eyes exhibited an increased immunoreactivity against the inflammatory C-reactive protein in the RPE/Bruch's membrane/choroid complex, whereas significantly less immunoreactivity for the major soluble complement inhibitor, complement factor H (CFH) <sup>120</sup>. Likewise, serum pro-inflammatory cytokines (e.g., IL-22) were significantly increased in AMD patients compared to age-matched controls <sup>121</sup>. Finally, age-related impairment of glial cells (Müller cells, astrocytes) has also recently been discussed as a potential initial cause of deficient retinal homeostasis and AMD development <sup>122-124</sup>.

### 1.1.3 Treatment and Emerging Therapies in AMD

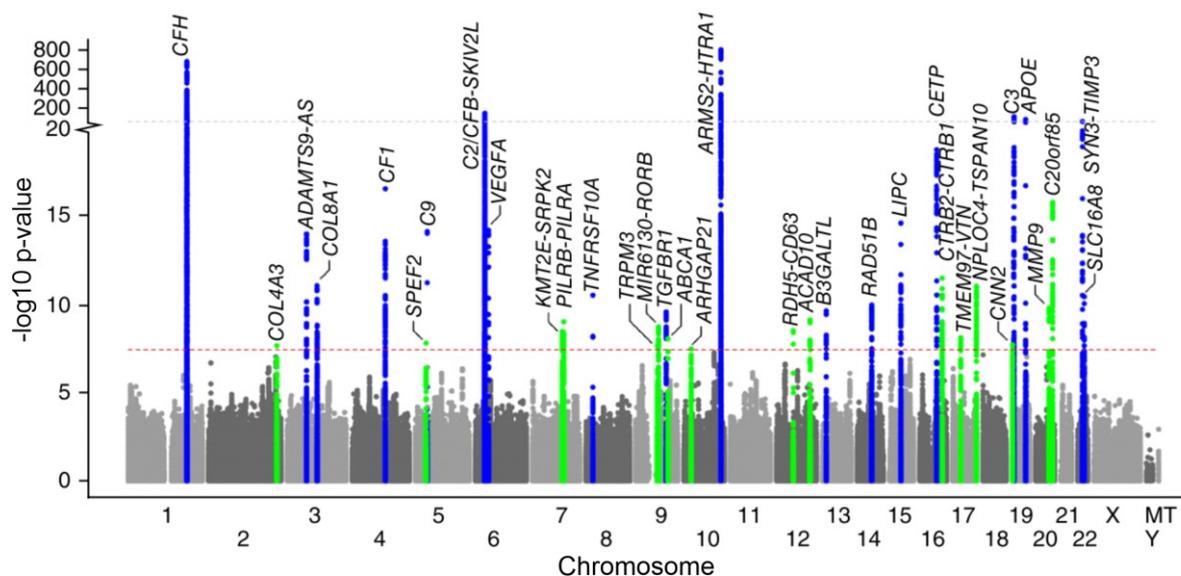

The incomplete understanding of AMD pathogenesis and the heterogeneity of its phenotypic expression has slowed the development of effective therapies. The use of therapeutics that inhibit VEGF, a key mediator of choroidal neoangiogenesis <sup>125</sup>, has become the gold standard of treatment for NV-AMD, however only allowing temporary effects of improvement of exudative damage in the retina. Available on the market in the early 2000s, these inhibitors replaced laser therapy approaches previously used to ablate abnormal blood vessels <sup>126-128</sup>. Although different anti-VEGF agents are available nowadays, including antibodies and recombinant receptor-like proteins, the need for repeated intravitreal injections, recurrences and large variability in response are burdensome for patients <sup>1,129</sup>. Several clinical trials are currently testing gene therapy approaches for the sustained delivery of a range of angiostatic proteins <sup>130</sup>. Of interest, subretinal or intravitreal delivery of adeno-associated virus (AAV) vectors expressing soluble VEGF-neutralizing proteins has been shown to be safe in clinical trials <sup>131,132</sup>. Since multiple pathogenic pathways such as angiogenesis, complement activation and inflammation are involved in NV-AMD, multitarget gene therapy strategies addressing multiple genes or proteins are gaining increasing interest <sup>133</sup>.

Unlike for NV-AMD, there are no approved therapeutic options for GA-AMD. Given the known involvement of abnormal complement system activation in the pathogenesis of AMD <sup>134</sup>, many clinical trials are underway to investigate the effect of complement-targeted therapies to halt or delay disease progression to the atrophic form. These include the use of complement C3 and C5 inhibitors <sup>135,136</sup>, as well as AAV-mediated supplementation of

complement factor inhibitor (CFI) <sup>137</sup>. In addition, neuroprotection, visual cycle modulators, cell-based therapies and anti-inflammatory agents are currently under investigation <sup>129</sup>.

## 1.2 The Genetics of AMD

The role of genetics in AMD development is supported by several lines of evidence, including increased risk of AMD among the relatives of patients <sup>138,139</sup> and twin pairs, with higher disease rates in monozygotic than in dizygotic twins <sup>140,141</sup>. Furthermore, genome-wide linkage screens, candidate gene studies and genome-wide association studies (GWAS), have identified multiple genetic variants that influence AMD susceptibility <sup>142,143</sup>. Based on genome-wide genotyping data, GWAS compare in a hypothesis-free approach the allelic frequency of hundreds of thousands of genetic variants, particularly single nucleotide polymorphisms (SNPs), between a large cohort of probands with a given trait or disease (cases) and healthy controls. This allows the identification of genomic regions harbouring DNA sequence variations that are statistically associated with the disease or trait of interest <sup>144</sup>. Through these studies, precise information has been obtained on the genomic location of genetic variants that may influence susceptibility to AMD. Using only 50 controls and 96 cases, the first GWAS for AMD identified genetic variants around the *CFH* gene to be reproducibly associated with AMD <sup>118</sup>. This initial study was followed by several GWAS, which included an increasing number of individual DNA samples, consequently revealing additional AMD-associated loci <sup>145</sup>. The currently largest GWAS for AMD was published in 2016 by the International AMD Genomics Consortium (IAMDGC), which compared >12 million variants between 16,144 patients with advanced AMD and 17,832 controls in a European cohort <sup>119</sup>. In this study, 52 independent genetic variants across 34 loci were found to be linked to the AMD phenotype with genome-wide significance ( $p < 5 \times 10^{-8}$ ) (**Figure 3**). Despite these advances, for most of the associated variants the molecular and biological significance remains to be functionally clarified.

**Figure 3: AMD-associated loci from the International AMD Genomics Consortium (IAMDC) GWAS.**

Genome-wide single variant association analysis for >12 million variants in 16,144 advanced AMD patients vs. 17,832 controls. Shown is the Manhattan plot exhibiting p-values for association. The horizontal red line indicates genome-wide significance ( $p < 5 \times 10^{-8}$ ). In green novel genome-wide significant loci associated with AMD, in blue previously known AMD loci. Despite the great potential of the analysis, for most of the associated variants within susceptible loci the molecular and biological significance remains to be functionally investigated. (Figure taken from Fritsche et al., 2016<sup>119</sup>).

### 1.2.1 From GWAS-associated Genetic Loci to Causal Susceptibility Variants

GWAS susceptible loci are typically named after the gene(s) showing the closest physical proximity to the genetic variant revealing the most significant association with the disease or trait of interest (the so-called lead variant) (**Figure 3**). These loci typically include multiple variants that may contribute to the association signal. Very often these variants are in linkage disequilibrium (LD) with each other, which tend to be inherited together during the meiotic recombination process<sup>146-148</sup>. LD results in multiple variants present within a certain locus by virtue of this correlation. The LD structure of genetic loci is exploited by GWAS studies to impute subsets of SNPs in addition to those directly interrogated by genotyping. This results in the availability of genetic markers that tag (or co-occur with) actual associated variants in complex traits<sup>148,149</sup>. However, the phenomenon of LD makes it difficult to identify variants that specifically underlie the association signal at a GWAS-associated locus (causal variant) from the physically close non-causal variants in LD<sup>148,150</sup>.

The determination of the actual causal variant is fundamental to obtain biological insights from the list of associations provided by GWAS, allows to identify target genes and, especially, to connect causal variants and target genes to molecular, cellular, and physiological phenotypes. In order to assess the contribution of each variant to the association signal detected by GWAS, a dissection of a GWAS-identified locus aimed at clarifying the relationship between identified variants is crucial<sup>151</sup>. Numerous post-GWAS analysis strategies, including statistical methods and functional genomic annotations, have been widely applied to prioritise causal variants (referred to as fine mapping) and their target

genes<sup>151,152</sup>. Statistical approaches focus mainly on the strength of the association signal<sup>151,152</sup>. Conditional analysis of the regional variants is often used to estimate the number of variants at a susceptible locus that are associated with disease or trait of interest independent from each other. The conditional approach is based on an iterative association analysis of most GWAS-identified variants that include lead or other selected variants as covariates. If a neighbouring variant remains significant, it is interpreted as a distinct association signal<sup>153</sup>. Variants related to independent association signals identified by conditional analysis can be further sorted based on their respective p- or LD values. A common approach is to consider, for example, all SNPs with a p-value below  $5 \times 10^{-8}$  (standard p-value for genome-wide significance) as candidates for causality<sup>154</sup>. Alternatively, posterior probabilities of causality can be assigned to each variant of a given locus using the Bayesian method. This approach assumes that each locus associated with GWAS harbours exactly one causal variant and provides minimal sets of variants that contain the causal variant with 95% probability (95% credible interval)<sup>154,155</sup>.

Fine mapping is followed by a full mechanistic analysis of a GWAS-identified locus to identify the immediate effects of causal variants, the gene(s) involved in the locus that mediate the disease association, and the downstream effects on networks or pathways that lead to changes in cellular and physiological function<sup>156,157</sup>. Only 2-3% of GWAS hits fine-map to coding variants<sup>144</sup>. Such variants are a first choice to be considered for causality, as they are expected to change the amino acid sequence of an encoded protein with structural and functional implications. The causative gene candidates and underlying molecular mechanism can thus be suggested based on the genomic position and the type of the coding variant (e.g., non-synonymous, nonsense, or frameshift variant)<sup>156,158</sup>. Non-coding variants including intragenic or deep-intronic, mostly cannot be directly linked to a causative candidate gene, making interpretation of possible functional consequences difficult<sup>159,160</sup>. These variants are thought to exert regulatory effects on target gene expression through mechanisms such as promoter modification and enhancer or silencer activity<sup>160</sup>. Colocalization of non-coding variants with genomic regulatory regions, e. g. by correlation analysis between those variants and gene expression (known as eQTL analysis), DNA methylation or transcription factor binding makes it possible to link non-coding variants to their target genes and reveal their potential functional consequences<sup>144,156,161,162</sup>. Finally, pathway enrichment analyses assess overrepresentation of a group of functionally related SNPs or genes in particular biological pathways and serve to evaluate signals that might be biologically significant but are overlooked among numerous potentially false positive signals<sup>163</sup>.

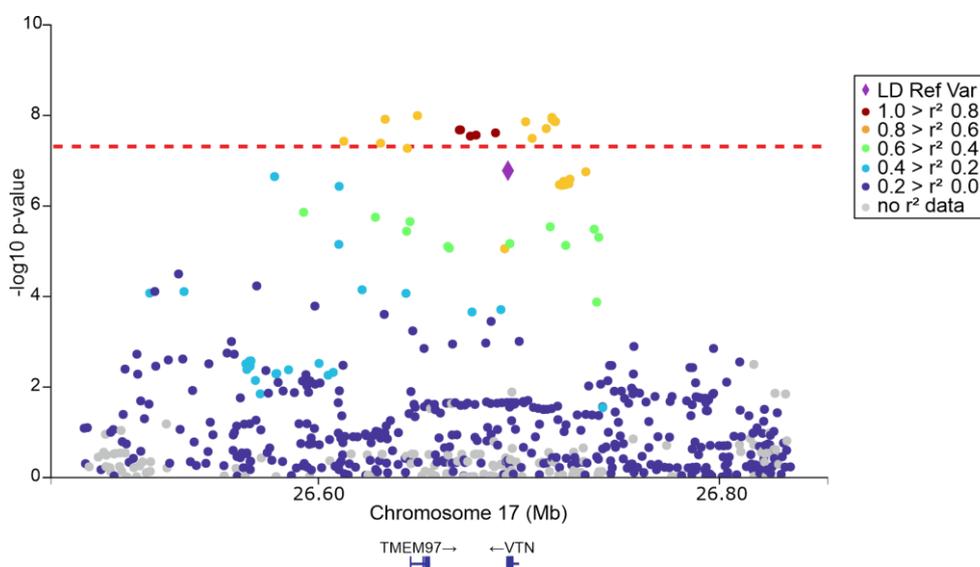

Statistical fine mapping and functional annotation of GWAS findings have so far revealed a variety of candidate variants and genes of potential relevance to AMD pathogenesis. These include genes related to ECM organisation and function, key regulators in immune defence,

as well as lipid/cholesterol metabolism and trafficking <sup>119</sup>. Experimental functional analyses of these candidate genes are mandatory to unequivocally establish their causality.

### 1.2.2 Genetic Variant rs704 and Its Association With AMD

Among the SNPs successfully genotyped in the GWAS by Fritsche and colleagues, the non-synonymous variant rs704, located within the *VTN* gene on chromosome 17 (17q11.2), was strongly associated with AMD ( $p = 1.71 \times 10^{-7}$ ) <sup>119</sup>. In the European population, rs704 represent a common polymorphism with an estimated gene frequency of about 51% for the ancestral C allele and 49% for the alternative T allele <sup>164</sup>.

Found in high LD ( $r^2 > 0.6$ ) with lead variant rs11080055 located in intron 1 of the *TMEM97* gene (**Figure 4**), rs704 is part of a 95% credible set of 22 genetic variants at the AMD-associated *TMEM97-VTN* locus. Within this 95% credible interval, rs704 is the only missense and protein-altering variant, thus receiving a high priority score for SNP causality. Located in exon 7 of the *VTN* gene, variant rs704 leads to a cytosine (C) to thymine (T) substitution at nucleotide position 1199, resulting in a threonine to methionine amino acid exchange at amino acid position 400 (T400M) of the encoded vitronectin protein. Given the previously reported detection of vitronectin in AMD-related retinal tissues and deposits <sup>42,165,166</sup>, this variant appeared to be an excellent candidate for targeted functional analysis.

**Figure 4: Association of genetic variant rs704 with late-stage AMD.**

The rs704 association signal within the *TMEM97/VTN* locus were plotted using LocusZoom <sup>167</sup> and the GWAS summary statistics published by Fritsche and colleagues <sup>119</sup>. Each dot represents a genetic variant and is plotted according to its AMD association displayed by its  $-\log_{10}(p\text{-value})$ . The horizontal red line indicates genome-wide significance ( $p < 5 \times 10^{-8}$ ). Variant rs704 is presented as a purple diamond and serves as a reference linkage disequilibrium (LD) variant. LD between variants is symbolised by a range of colours from red (complete LD,  $r^2=1$ ) to dark blue (no LD,  $r^2=0$ ). Transcript map with direction of transcription is given at the bottom. (LocusZoom plot was exported and modified from <https://my.locuszoom.org/gwas/894486/region/?chrom=17&start=26194861&end=27194861>, accessed on 9 May 2022).

In addition to AMD, rs704 has been linked to other traits, such as vascular tumours in patients with the Von Hippel–Lindau gene defect <sup>168</sup>, altered concentration of circulating

lipoproteins and apolipoproteins with risk of coronary artery disease<sup>169,170</sup>, as well as radiation pneumonitis in lung cancer patients<sup>171</sup>. Furthermore, normal cognitive processing and blood pressure were also associated to rs704<sup>172,173</sup>.

### 1.3 Vitronectin

The genetic variant rs704 causes an amino acid substitution in vitronectin, a secreted glycoprotein abundant in human blood plasma (0.2-0.5 mg/ml), e.g., as a component of high-density lipoproteins<sup>174,175</sup>, and in the ECM of various tissues, including the retina<sup>29,176-178</sup>.

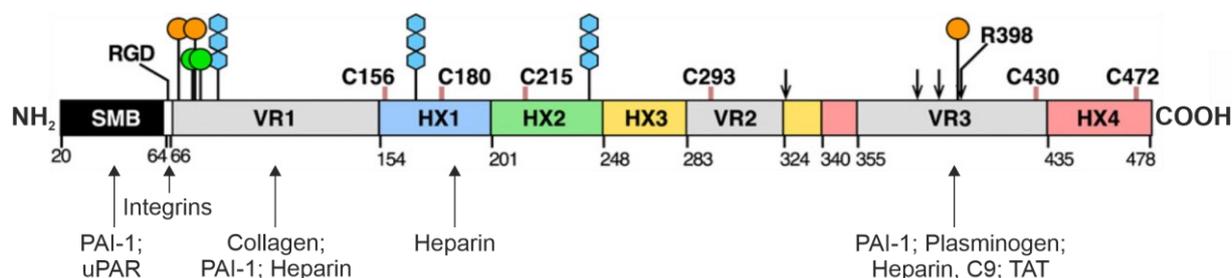

#### 1.3.1 Vitronectin Expression, Structure and Processing

While vitronectin is mainly synthesised in the liver<sup>179</sup>, it is also expressed in the brain<sup>180</sup>, in vascular smooth muscle cells<sup>181</sup> and in the retina<sup>165,182</sup>. The full-length protein comprises 478 amino acids. It contains a signal peptide (the first 19 amino acid residues) which is cleaved off during cellular secretion. Secreted mature vitronectin comprises 459 amino acids organised in several structural domains (**Figure 5**), including three N-glycosylation motifs and potential sites for sulphation and post-translational phosphorylation interspersed within the domain structure of vitronectin<sup>178,183</sup>. The first 44 amino acids at the N-terminal site of the mature protein form the somatomedin domain (SMD), with a partial 3<sub>10</sub>-helix and a single turn  $\alpha$ -helix as its classical secondary structural elements<sup>184</sup>. The SMD motif mediates the binding of vitronectin to plasminogen activator inhibitor 1 (PAI-1)<sup>185,186</sup> and urokinase plasminogen activator receptor (uPAR)<sup>187</sup>. This enables vitronectin regulation of PAI-1- and uPAR-associated biological processes, such as haemostasis, angiogenesis, cell adhesion and motility<sup>186,188,189</sup>. Next, an arginine-glycine-aspartate (RGD) motif follows, which represents the main vitronectin binding site for integrin receptors<sup>190</sup>, and thus the cell attachment site. Through RGD-mediated integrin binding, vitronectin activates intracellular signalling pathways, including the MAP kinase pathway which regulates cell adhesion, spreading, migration, proliferation, and apoptosis<sup>191-194</sup>.

The major proportion of vitronectin is composed of three variable regions and four hemopexin (HX)-like repeats that fold as a single four-bladed  $\beta/\alpha$  thruster, known as the HX domain<sup>195</sup>. The variable regions exhibit low conservation and low conformation order. Variable region 1 (amino acid 66 to 154) hosts a binding site for collagen and heparin, as well as phosphorylation, sulfation, and N-glycosylation sites<sup>178,195,196</sup>. Furthermore, an additional site for PAI-1 binding was recently reported within this region<sup>197,198</sup>. Variable region 2 (amino acid 283 to 324) is only slightly variable and located very close to thrombin cleavage sites. Variable region 3 (amino acid 355 to 435) shows high variability and contains a furin cleavage site at residue R398<sup>195</sup>. It also harbours binding sites for heparin<sup>195</sup>, complement component C9, plasminogen, PAI-1 and the thrombin/antithrombin complex<sup>199-201</sup>. *Via* the HX domain, vitronectin binds to soluble ionic calcium and crystalline

hydroxyapatite<sup>202</sup>. Calcium binding by vitronectin was recently proposed to be crucial in the formation of abnormal extracellular deposits, such as those associated with AMD<sup>202</sup>. Among complement factors, vitronectin also binds the terminal complement complex C5b-7, however the domain used by vitronectin for this interaction is debated and has so far implicated both the heparin and non-heparin binding sites<sup>178,203</sup>. Near the RGD domain and within the C-terminal portion, vitronectin additionally possesses binding domains for several bacterial pathogens<sup>196</sup>.

The full-length three-dimensional structure of the vitronectin protein has not yet been experimentally resolved<sup>197</sup>. Crystallographic studies are challenged by the conformational lability and heterogeneity of vitronectin both *in vitro* and *in vivo*. The protein normally circulates as a mixture of single-chain and disulphide cross-linked two-chain form which is produced by furin-mediated cleavage on the carboxy-terminal side of R398<sup>204</sup> consisting of a heavy chain (65 kDa) and a C-terminal light chain of approximately 10 kDa molecular weight<sup>204</sup> connected *via* a disulphide bridge between C293 and C472<sup>178</sup>. Recently, Shin and colleagues proposed that the two-chain form of vitronectin is further maintained by the central structure of its HX domain, with the chains linked by disulphide bonds between C156 and C472<sup>195</sup>. Moreover, although the majority of circulating vitronectin is monomeric, the tissue form of the protein adopts an altered, multimeric conformation<sup>205</sup>: Unfolding of vitronectin due to protease activity and/or physical binding with specific interaction partners results in self-association into multimeric aggregates. Such higher ordered forms of vitronectin were specifically detected in the ECM and within platelet  $\alpha$ -granules<sup>205,206</sup>. The multimeric state reveals previously cryptic sites that enhance vitronectin activity<sup>205,207</sup>. As a result, the multimeric form of vitronectin represents a more potent molecule, binding to ligands with higher affinity than native vitronectin<sup>208</sup>. Finally, extensive posttranslational modifications (e.g., N-linked glycosylation, phosphorylation, and sulphation) increase the structural heterogeneity of this protein<sup>183</sup>.

**Figure 5: Domain organization of vitronectin.**

Representation of vitronectin domains: the somatomedin domain (SMB) (in black), the RGD sequence (in white), the four hemopexin domains (HX) (in blue, green, yellow, and pink) and the three variable regions VR1 to VR3 (in grey). Also shown are the cysteines (C) (pink lines) and the sites of phosphorylation (orange circles), sulphation (green circles), N-glycosylation (blue hexagons) and cleavage by proteases (arrows). Binding sites for vitronectin interaction partners are indicated for each domain and involve binding for plasminogen activator inhibitor 1 (PAI-1), urokinase plasminogen activator receptor (uPAR), integrin receptors, collagen, heparin, plasminogen, complement factor 9 (C9) and thrombin/antithrombin complex (TAT). (Figure modified from Shin et al., 2019<sup>195</sup>).

### 1.3.2 Functionality of Vitronectin

Vitronectin functions as a potent matricellular factor, coordinating a variety of cellular processes like cell adhesion, migration, angiogenesis, complement activation, tissue remodelling and growth factor signalling at the cell-ECM interface<sup>177,178</sup>, all processes which have also been associated with AMD pathogenesis<sup>134,209-211</sup>.

Extracellular vitronectin acts as a bond between cells and ECM promoting cell attachment to the ECM<sup>178</sup>. These adhesive properties are mediated by the binding of vitronectin to cellular transmembrane integrin receptors. After vitronectin binding to these receptors, actin microfilaments of the cytoskeleton connect to integrin to form focal adhesions and evoke a molecular clutch<sup>178,212</sup>. On the other hand, vitronectin also promotes cell adhesion in an integrin-independent manner. By binding to the urokinase receptor uPAR, vitronectin triggers a crosstalk between these receptors and integrins upon membrane tension, also resulting in integrin activation and subsequent focal adhesion formation<sup>213,214</sup>. Furthermore, binding of vitronectin to cell surface-associated proteoglycans also appears to stimulate cell adhesion<sup>178</sup>. Through its adhesive properties, vitronectin is supposed to regulate many cellular processes, including the maintenance of endothelial barrier function<sup>215,216</sup>, the role of adherent leukocytes enhancing the chronic inflammatory phase<sup>217,218</sup>, or tumour development and progression<sup>219,220</sup>.

Through binding to integrin  $\alpha v \beta 3$  on endothelial cells, vitronectin has been observed to activate vascular endothelial growth factor receptor 2 (VEGFR-2), thereby contributing to the regulation of angiogenesis mediating processes such as adhesion, migration, and proliferation<sup>221</sup>. In line with this, binding of vitronectin to integrins and uPAR appears to be required for the survival and maturation of new blood vessels in several vascular beds, including the retina<sup>177,222</sup>.

Vitronectin is furthermore involved in regulating the terminal pathway of complement activation to limit the self-reactivity of the innate immune response<sup>178</sup>. Specifically, it binds to complement proteins C5b-7 and C9 to prevent their cell membrane insertion and polymerisation, respectively. This ultimately prevents the formation of the membrane attack complex (MAC) and thus the creation of cytotoxic pores on the cell surface<sup>178,201</sup>. This process may be particularly important in vitronectin-rich sites (i.e., the vessel wall), implying that these sites may be protected from autologous complement attack<sup>178</sup>. In addition, vitronectin mediates complement escape and cell invasion of microbial pathogens that recruit vitronectin to their cell surfaces by exploiting its adhesive properties<sup>196,223</sup>.

Through interaction with the urokinase plasminogen activator (uPA), its receptor uPAR, integrins and PAI-1, vitronectin is also part of the plasminogen activation system, an extracellular proteolytic enzyme system involved in the regulation of cell migration, fibrinolysis, ECM degradation, tissue remodelling and inflammation<sup>224</sup>. Specifically, the

binding of uPA to uPAR promotes extracellular proteolysis by activating plasmin from inactive plasminogen. Once activated, the plasmin system causes the degradation of fibrin (fibrinolysis), several blood clotting factors and ECM components, including also vitronectin<sup>224</sup>. Binding of vitronectin to uPAR promotes cell adhesion and migration in a uPA-stimulated manner<sup>213,225</sup>. Through allosteric modulation, vitronectin prolongs the half-life of PAI-1, the major inhibitor of uPA<sup>226</sup>. PAI-1 competitively displaces adhesion receptors from vitronectin, and thus can detach cells from ECM<sup>227-229</sup>.

Finally, vitronectin also regulates blood system-related protein cascades such as coagulation and fibrinolysis through its interaction with heparin and thrombin-antithrombin III<sup>177,230</sup>. In the presence of vitronectin, the antithrombotic and procoagulant functions of heparins and thrombin are neutralised<sup>177,230</sup>. This is in addition to the enhanced thrombin-inhibiting properties of PAI-1 resulting from the interaction of PAI-1 with vitronectin<sup>177</sup>.

### 1.3.3 Contribution of Vitronectin to AMD Development

In the retina, vitronectin mRNA expression was detected in the RPE, photoreceptors and ganglion cells<sup>165,166</sup>, with higher expression in the neural retina than in the RPE<sup>231</sup>. However, extracellular detection of vitronectin protein in the retina was mainly restricted to Bruch's membrane and the retinal vasculature<sup>165</sup>. In particular, the inner collagenous layer of Bruch's membrane<sup>29</sup> and the basement membrane of endothelial cells<sup>232</sup> contain significant amounts of vitronectin. During AMD development, altered vitronectin expression and deposition in the retina was described: Retinal tissue sections from donors with a clinical diagnosis of atrophic AMD showed significant vitronectin immunoreactivity in the cytoplasm of RPE cells<sup>233</sup>. Furthermore, manifold immunocytochemical and proteomic analysis of human eye donor tissues supported the localisation of vitronectin in drusen and suggested this protein as the main constituent and marker of extracellular deposits associated with AMD, but also with Alzheimer disease, atherosclerosis, and other degenerative disorders<sup>40-42,166</sup>. Recently, Dr Marassi's group suggested that the ability of vitronectin to bind soluble calcium ions and mineralised hydroxyapatite is the initiating factor in the formation of abnormal calcified protein-lipid extracellular deposits that accumulate with AMD progression<sup>202</sup>. Additionally, although vitronectin was also visualised in areas of intact RPE without drusen, the greatest immunoreactivity was reported in RPE cells flanking or overlying drusen and in small sub-RPE deposits containing RPE cell debris<sup>233</sup>. Consistent with this, vitronectin mRNA expression was increased in hiPSC-RPE cells generated from patients with a history of AMD compared to cells derived from healthy donors<sup>234</sup>.

In addition to AMD-associated alterations of vitronectin expression and deposition in the retina, mass spectrometry-based expression analysis of plasma proteins from 255 AMD patients and 221 controls revealed an association between altered plasma vitronectin concentrations and AMD<sup>235</sup>. Finally, an upregulation of vitronectin in the aqueous humour of

patients with NV-AMD with little or no response to anti-VEGF treatment was detected in comparison to the healthy control group, suggesting an involvement of this protein also in biological events underlying vascular complications in AMD <sup>236</sup>.

#### 1.3.4 Effect of rs704 on Vitronectin

Only few studies addressed the impact of rs704 on vitronectin: In 1990, Tollefsen and colleagues showed that rs704 affects the cleavage of vitronectin *in vivo* <sup>237</sup>. Specifically, the rs704-induced amino acid exchange T400M renders vitronectin less susceptible to proteolytic cleavage at R398 <sup>237</sup>. This leads to an increase in the 75 kDa single-chain form of the protein and to a reduction in the cleaved, disulphide-bound two-chain form composed of the 65 kDa and 10 kDa subunits <sup>237-239</sup>. These two physiological isoforms of vitronectin revealed a distinct conformation as suggested by different susceptibility to protein kinase A, an enzyme which phosphorylates vitronectin in plasma <sup>240</sup>. Chain and colleagues reported that protein kinase A can only phosphorylate the single-chain form but not the two-chain form of vitronectin, due to burial and inaccessibility of the phosphorylation site in the two-chain form <sup>239,241</sup>. However, after binding of the two-chain vitronectin to heparin <sup>242</sup>, the phosphorylation site becomes exposed and capable to undergo phosphorylation at physiological pH <sup>239,241</sup>. Finally, a proteomic analysis of human plasma from 3,301 individuals revealed an impact of rs704 on vitronectin protein expression in blood, which identified this polymorphism as a protein quantitative trait locus (pQTL) <sup>243</sup>.

#### 1.4 Aim of the Study

Despite considerable research efforts, the aetiology of AMD is far from being fully understood, and much remains elusive about the pathophysiological events that lead to the disease. Although GWAS studies strongly suggest the contribution of genomic variation in AMD susceptibility, the translation of GWAS findings into clinical aspects of the disease is limited by the difficulty of interpreting GWAS results and the notable lack of follow-up laboratory studies of suggested causal candidate variants/genes <sup>244</sup>. A functional validation of the causal variants and their targets would facilitate the understanding of the molecular and cellular mechanisms of the disease and would allow the identification of useful biomarkers for preventive and/or therapeutic purposes. To this end, the present study aimed to explore the functional meaning of the statistical association of *VTN*-related genetic variant rs704 with AMD and by that to provide a deeper insight into the contribution of the two vitronectin isoforms to AMD pathology. Based on a comparison of the non-AMD risk-associated vitronectin isoform (*VTN*\_rs704:C) and the AMD risk-associated isoform (*VTN*\_rs704:T), this study first assessed the impact of rs704 on vitronectin protein expression, secretion, processing, stability, multimerization, as well as the ability to bind to cell surfaces. In addition, the role of vitronectin and the impact of rs704 on vitronectin functionality were followed in

AMD-associated cellular processes such as cell adhesion, autophagy, viability, migration, and ECM deposition. Finally, the impact of rs704 on the interaction of vitronectin with its interaction partner PAI-1 was studied. The results of these investigations will provide a basis for further understanding one aspect of AMD pathogenesis in the hope of ultimately facilitating the development of novel strategies for treatment and prevention of this devastating disease.

## 2. Materials

### 2.1 Eukaryotic Cell Lines

Table 1: Name, origin and source of cell lines used in this work

| Cell Line   | Organism of origin  | Tissue of origin                | Source   |
|-------------|---------------------|---------------------------------|--|
| HEK293-EBNA | <i>Homo sapiens</i> | Embryonic kidney                | (Invitrogen) Thermo Fisher Scientific, Waltham, MA, USA        |
| ARPE-19     | <i>Homo sapiens</i> | Retinal pigment epithelium      | ATCC; LGC Standards GmbH, Wesel, Germany                       |
| hiPSC-RPE   | <i>Homo sapiens</i> | Dermal skin or peripheral blood | Institute of Human Genetics, University of Regensburg, Germany |
| HUVEC       | <i>Homo sapiens</i> | Umbilical cord vein             | Life Technologies, Carlsbad, CA, USA                           |
| Y-79        | <i>Homo sapiens</i> | Retinoblastoma                  | ATCC; LGC Standards GmbH, Wesel, Germany                       |
| WERI-Rb1    | <i>Homo sapiens</i> | Retinoblastoma                  | ATCC; LGC Standards GmbH, Wesel, Germany                       |

### 2.2 Escherichia (E.) Coli Strains

*E. coli* strain DH5 $\alpha$  from Life Technologies (Carlsbad, CA, USA) was used in this work.

### 2.3 Oligonucleotide Primers and Probes for PCR and Sequencing Reactions

Table 2: Name, sequences, target genes and application of oligonucleotides primers and probes used in this work

qRT-PCR: quantitative real-time reverse transcription (RT)-PCR; T<sub>a</sub>: annealing temperature

All oligonucleotides were purchased from Metabion (Planegg, Germany) except for those used for qRT-PCR which were purchased from Sigma-Aldrich (St. Louis, MO, USA).

## 2.4 Plasmids and Expression Constructs

Table 3: Name, application and source of plasmids and expression constructs used in this work

| Plasmid name             | Application  | Source   |
|--------------------------|--|--|
| pGEM®-T                  | Cloning vector                                     | Promega Corporation, Madison, WI, USA                          |
| pCDNA3.1                 | Expression vector                                  | Thermo Fisher Scientific, Waltham, MA, USA                     |
| pEXPR-IBA103             | Expression vector                                  | Iba Life Sciences, Götting, Germany                            |
| pCDNA3.1-GFP             | Expression of recombinant GFP                      | Institute of Human Genetics, University of Regensburg, Germany |
| pcDNA3.1-VTN_rs704:C     | Expression of recombinant VTN_rs704:C              | Institute of Human Genetics, University of Regensburg, Germany |
| pcDNA3.1-VTN_rs704:T     | Expression of recombinant VTN_rs704:T              | Institute of Human Genetics, University of Regensburg, Germany |
| pEXPR-IBA103-VTN_rs704:C | Expression of recombinant Strep-tagged VTN_rs704:C | Institute of Human Genetics, University of Regensburg, Germany |
| pEXPR-IBA103-VTN_rs704:T | Expression of recombinant Strep-tagged VTN_rs704:T | Institute of Human Genetics, University of Regensburg, Germany |
| pcDNA3.1-PAI-1           | Expression of recombinant PAI-1                    | Generated during this work                                     |
| pEXPR-IBA103-PAI-1       | Expression of recombinant Strep-tagged PAI-1       | Generated during this work                                     |

## 2.5 Primary Antibodies

Table 4: Name, origin, application, and source of primary antibodies used in this work

| Antibody                 | Class | Host species | Dilution | Application | Source                               |
|--------------------------|-------|--------------|----------|-------------|--------------------------------------|
| Anti-ACTB (A5441)        | mAB   | mouse        | 1:10000  | WB          | Sigma-Aldrich, St. Louis, MO, USA    |
| Anti-ATP1A1 (55187-1-AP) | pAB   | rabbit       | 1:100    | IF          | Proteintech Group, Rosemont, IL, USA |
| Anti-ATP1B1              | pAB   | rabbit       | 1:100    | IF          | Proteintech Group,                   |

|   |     |        |                  |          |   |
|---|-----|--------|------------------|----------|---|
| (15192-1-AP)  |     |        |                  |          | Rosemont, IL, USA   |
| Anti-BEST1<br>(ab2182)  | mAB | mouse  | 1:500            | IF       | Abcam, Cambridge,<br>United Kingdom                             |
| Anti-C9<br>(ab17931)  | mAB | mouse  | 1:100            | IF       | Abcam, Cambridge,<br>United Kingdom                             |
| Anti-CFH<br>(ab121056)  | mAB | mouse  | 1:100            | IF       | Abcam, Cambridge,<br>United Kingdom                             |
| Anti-COL V<br>(ab6582)  | pAB | rabbit | 1:100            | IF       | Abcam, Cambridge,<br>United Kingdom                             |
| Anti-COL VI<br>(SD83-03)  | mAB | rabbit | 1:100            | IF       | ThermoFisher<br>Scientific, Waltham,<br>MA, USA                 |
| Anti-ELA<br>(324756)  | pAB | rabbit | 1:100            | IF       | (Calbiochem) Merck<br>KGaA, Darmstadt,<br>Germany               |
| Anti-FN<br>(F7387)  | mAB | mouse  | 1:100            | IF       | Sigma-Aldrich, St.<br>Louis, MO, USA                            |
| Anti-GFP<br>(sc-8334)   | pAB | rabbit | 1:10000          | WB       | Santa Cruz<br>Biotechnology, Dallas,<br>TX, USA                 |
| Anti-LAM<br>(ab11575)   | pAB | rabbit | 1:100            | IF       | BIOZOL Diagnostica<br>Vertrieb GmbH,<br>Eching, Germany         |
| Anti-LC3B<br>(D11) XP®<br>(3868S)   | mAB | rabbit | 1:1000 in<br>BSA | WB       | Cell Signaling<br>Technology, Danvers,<br>MA, USA               |
| Anti-MAP<br>Kinase<br>(ERK1/2)<br>(M5670)   | pAB | rabbit | 1:2000 in<br>BSA | WB       | Sigma-Aldrich, St.<br>Louis, MO, USA                            |
| Anti-PAI-1<br>(11907S)  | mAB | rabbit | 1:1000<br>1:100  | WB<br>IF | Cell Signaling<br>Technology, Danvers,<br>MA, USA               |
| Anti-TIMP3<br>(MAB3318)   | mAB | mouse  | 1:100            | IF       | Sigma-Aldrich, St.<br>Louis, MO, USA                            |

WB: Western Blot; IF: Immunofluorescence staining; mAB: monoclonal antibody. pAB: polyclonal antibody  
Indicated in brackets are manufacturer's product catalogue numbers where available.

Unless labelled “in BSA” (antibodies prepared in BSA-based solution) (see Table 11), all antibodies used in the western blot analysis were prepared in a milk-based antibody solution (see Table 11).

## 2.6 Secondary Antibodies

Table 5: Name, origin, application, and source of secondary antibodies used in this work

| Antibody                                   | Dilution | Application | Source                                      |
|--|----------|-------------|---|
| Goat anti-mouse IgG, peroxidase-conjugate  | 1:10000  | WB          | (Calbiochem) Merck KGaA, Darmstadt, Germany |
| Goat anti-rabbit IgG, peroxidase-conjugate | 1:10000  | WB          | (Calbiochem) Merck KGaA, Darmstadt, Germany |
| Goat anti-mouse IgG, Alexa Fluor®594       | 1:800    | IF          | Life Technologies, Carlsbad, CA, USA        |
| Goat anti-mouse IgG, Alexa Fluor®488       | 1:800    | IF          | Life Technologies, Carlsbad, CA, USA        |
| Goat anti-rabbit IgG, Alexa Fluor®594      | 1:800    | IF          | Life Technologies, Carlsbad, CA, USA        |
| Goat anti-rabbit IgG, Alexa Fluor®488      | 1:800    | IF          | Life Technologies, Carlsbad, CA, USA        |

WB: Western Blot; IF: Immunofluorescence staining

## 2.7 Enzymes

Table 6: Name and source of enzymes used in this work

| Enzyme                                 | Source   |
|--|--|
| Antarctic phosphatase                  | New England Biolabs, Ipswich, MA, USA                  |
| EcoRI-HF (restriction enzyme)          | New England Biolabs, Ipswich, MA, USA                  |
| GoTaq® DNA-Polymerase                  | Promega Corporation, Madison, WI, USA                  |
| Papain                                 | Sigma-Aldrich, St. Louis, MO, USA                      |
| RevertAid M-MuLV Reverse Transcriptase | (Fermentas) Thermo Fisher Scientific, Waltham, MA, USA |
| T4 DNA Ligase                          | New England Biolabs, Ipswich, MA, USA                  |
| TrypLE™ Select Enzyme, no phenol red   | Life Technologies, Carlsbad, CA, USA                   |
| Trypsin, TPCK-Treated                  | Thermo Fisher Scientific, Waltham, MA, USA             |
| Trypsin-EDTA (0.5%), no phenol red     | Life Technologies, Carlsbad, CA, USA                   |
| XhoI (restriction enzyme)              | New England Biolabs, Ipswich, MA, USA                  |

## 2.8 Molecular Weight Standards

Table 7: Molecular weight standards and their source used in this work

| <b>Molecular Weight Standard</b>                               | <b>Source</b>  |
|--|--|
| Color-coded Prestained Protein Marker, High Range (43-315 kDa) | Cell Signaling Technologies, Danvers, MA, USA          |
| Gene Ruler DNA Ladder Mix                                      | Thermo Fisher Scientific, Waltham, MA, USA             |
| NativeMark™ Unstained Protein Standard                         | (Invitrogen) ThermoFisher Scientific, Waltham, MA, USA |
| PageRuler™ Prestained Protein Ladder, 10 to 180 kDa            | Thermo Fisher Scientific, Waltham, MA, USA             |

## 2.9 Kit Systems

Table 8: Name and source of molecular biological kits used in this work

| <b>Kit system</b>                                 | <b>Source</b>   |
|---|---|
| BigDye Terminator v1.1, v3.1 Cycle Sequencing Kit | Thermo Fisher Scientific, Waltham, MA, USA              |
| CHEMICON PAI Activity Assay Kit                   | (Merck) Sigma-Aldrich, St. Louis, MO, USA               |
| Clarity Max™ Western Blotting Substrate           | Bio-Rad Laboratories GmbH, Munich, Germany              |
| Clarity™ Western Blotting Substrate               | Bio-Rad Laboratories GmbH, Munich, Germany              |
| KiCqStart® Probe Assays                           | (Merck) Sigma-Aldrich, St. Louis, MO, USA               |
| Lipofectamine™ 3000 Transfection Reagent          | Thermo Fisher Scientific, Waltham, MA, USA              |
| Mirus TransIT®-LTI Transfection Reagent           | Mirus Bio LLC, Madison, WI, USA                         |
| NucleoBond® Xtra                                  | MACHEREY-NAGEL GmbH & Co. KG, Düren, Germany            |
| NucleoSpin® Gel and PCR Clean-up                  | MACHEREY-NAGEL GmbH & Co. KG, Düren, Germany            |
| NucleoSpin® Plasmid                               | MACHEREY-NAGEL GmbH & Co. KG, Düren, Germany            |
| NucleoSpin® Tissue                                | MACHEREY-NAGEL GmbH & Co. KG, Düren, Germany            |
| PureLink™ RNA Micro Kit                           | (Invitrogen) Thermo Fisher Scientific, Waltham, MA, USA |
| RNase-Free DNase Set                              | Qiagen, Hilden, Germany                                 |
| Strep-tag® protein purification system            | Iba Life Sciences, Götting, Germany                     |
| Takyon™ Low Rox Probe MasterMix dTTP Blue         | Eurogentec, Seraing, Liège, Belgium                     |

## 2.10 Chemicals

Table 9: Name and source of chemicals used in this work

| <b>Chemical</b>       | <b>Source</b>                  |
|-----------------------|--------------------------------|
| 4-(2-hydroxyethyl)-1- | Merck KGaA, Darmstadt, Germany |

|   |  |
|---|--|
| piperazineethanesulfonic acid, C <sub>8</sub> H <sub>18</sub> N <sub>2</sub> O <sub>4</sub> S (HEPES)   |  |
| 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT)   | Sigma-Aldrich, St. Louis, MO, USA                  |
| 4',6-diamidino-2-phenylindole (DAPI)-Stain-solution   | Life Technologies GmbH, Darmstadt, Germany         |
| 5-Bromo-4-chloro-3-indolyl β-D-galactopyranoside, C <sub>14</sub> H <sub>15</sub> BrClNO <sub>6</sub> (X-Gal)   | AppliChem GmbH, Darmstadt, Germany                 |
| Acidic acid, CH <sub>3</sub> COOH   | Merck KGaA, Darmstadt, Germany                     |
| Ammonia solution 25%, NH <sub>4</sub> OH  | Merck KGaA, Darmstadt, Germany                     |
| Ammonium persulfate (APS), (NH <sub>4</sub> ) <sub>2</sub> S <sub>2</sub> O <sub>8</sub>  | AppliChem GmbH, Darmstadt, Germany                 |
| Ampicillin sodium salt, C <sub>16</sub> H <sub>18</sub> N <sub>3</sub> NaO <sub>4</sub> S   | Carl Roth GmbH + Co. KG, Karlsruhe, Germany        |
| bisBenzimide Hoechst (H) 33342 trihydrochloride, C <sub>27</sub> H <sub>28</sub> N <sub>6</sub> O·3HClx·H <sub>2</sub> O                                  | Sigma-Aldrich, St. Louis, MO, USA                  |
| Bromophenol blue sodium salt, C <sub>19</sub> H <sub>9</sub> Br <sub>4</sub> O <sub>5</sub> SNa   | Sigma-Aldrich, St. Louis, MO, USA                  |
| Calcium chloride, CaCl <sub>2</sub> , 2M  | Carl Roth GmbH + Co. KG, Karlsruhe, Germany        |
| Chloroquine, C <sub>18</sub> H <sub>26</sub> ClN <sub>3</sub>   | Merck KGaA, Darmstadt, Germany                     |
| Coomassie Brilliant Blue R-250 (sodium salt), C <sub>45</sub> H <sub>44</sub> N <sub>3</sub> NaO <sub>7</sub> S <sub>2</sub>                              | VWR International Germany GmbH, Darmstadt, Germany |
| Dimethyl sulfoxide (DMSO), C <sub>2</sub> H <sub>6</sub> OS   | AppliChem GmbH, Darmstadt, Germany                 |
| Disodium hydrogen phosphate, Na <sub>2</sub> HPO <sub>4</sub>   | Merck KGaA, Darmstadt, Germany                     |
| Dithiothreitol (DTT)  | Carl Roth GmbH + Co. KG, Karlsruhe, Germany        |
| Ethanol ≥99,8, C <sub>2</sub> H <sub>6</sub> O  | Carl Roth GmbH + Co. KG, Karlsruhe, Germany        |
| Ethidium bromide-solution 0,07%, C <sub>21</sub> H <sub>20</sub> BrN <sub>3</sub> in H <sub>2</sub> O   | AppliChem GmbH, Darmstadt, Germany                 |
| Ethylendiamintetraacetat disodium dihydrate salt, C <sub>10</sub> H <sub>14</sub> N <sub>2</sub> Na <sub>2</sub> O <sub>8</sub> ·2H <sub>2</sub> O (EDTA) | Merck KGaA, Darmstadt, Germany                     |
| Glucose, C <sub>6</sub> H <sub>12</sub> O <sub>6</sub>  | Merck KGaA, Darmstadt, Germany                     |
| Glutaraldehyde 25%, C <sub>5</sub> H <sub>8</sub> O <sub>2</sub> in H <sub>2</sub> O  | Carl Roth GmbH + Co. KG, Karlsruhe, Germany        |
| Glycerol 87%, C <sub>3</sub> H <sub>8</sub> O <sub>3</sub>  | University of Regensburg, Chemical Supplies        |
| Glycin, C <sub>2</sub> H <sub>5</sub> NO <sub>2</sub>   | AppliChem GmbH, Darmstadt, Germany                 |
| HiDi™ Formamide, CH <sub>3</sub> NO   | Thermo Fisher Scientific, Waltham, MA, USA         |
| Hydrochloric acid 1M, HCl   | Merck KGaA, Darmstadt, Germany                     |
| Hydrogen peroxide (H <sub>2</sub> O <sub>2</sub> ) 30%  | Sigma-Aldrich, St. Louis, MO, USA                  |
| Isopropanol, C <sub>3</sub> H <sub>8</sub> O  | Merck KGaA, Darmstadt, Germany                     |
| Isopropyl β-d-1-thiogalactopyranoside, C <sub>9</sub> H <sub>18</sub> O <sub>5</sub> S (IPTG)   | AppliChem GmbH, Darmstadt, Germany                 |
| L-Cysteine  | Sigma-Aldrich, St. Louis, MO, USA                  |
| Magnesium chloride, MgCl <sub>2</sub>   | Merck KGaA, Darmstadt, Germany                     |
| Methanol, CH <sub>4</sub> O   | Sigma-Aldrich, St. Louis, MO, USA                  |
| Paraformaldehyde (PFA), (CH <sub>2</sub> O) <sub>n</sub>  | AppliChem GmbH, Darmstadt, Germany                 |
| Peptone   | Carl Roth GmbH + Co. KG, Karlsruhe, Germany        |
| Potassium chloride, KCl   | Merck KGaA, Darmstadt, Germany                     |
| Potassium dihydrogen phosphate, KH <sub>2</sub> PO <sub>4</sub>   | Merck KGaA, Darmstadt, Germany                     |
| Sodium acetate trihydrate, CH <sub>3</sub> COONa·H <sub>2</sub> O   | Merck KGaA, Darmstadt, Germany                     |
| Sodium chloride, NaCl   | VWR International Germany GmbH, Darmstadt, Germany |
| Sodium dodecyl sulphate (SDS) ≥99%, C <sub>12</sub> H <sub>25</sub> NaO <sub>4</sub> S  | Carl Roth GmbH + Co. KG, Karlsruhe, Germany        |
| Sodium hydroxide, NaOH  | Merck KGaA, Darmstadt, Germany                     |
| Tetramethylethylenediamine (TEMED), (CH <sub>3</sub> ) <sub>2</sub> NCH <sub>2</sub> CH <sub>2</sub> N(CH <sub>3</sub> ) <sub>2</sub>                     | Merck KGaA, Darmstadt, Germany                     |
| Tris(hydroxymethyl)aminomethane (Tris), NH <sub>2</sub> C(CH <sub>2</sub> OH) <sub>3</sub>  | Affymetrix, Santa Clara, CA, USA                   |
| Tris-HCl  | VWR International Germany GmbH, Darmstadt, Germany |

|  |                                   |
|--|-----------------------------------|
| $\beta$ -Mercaptoethanol, HSCH <sub>2</sub> CH <sub>2</sub> OH | Sigma-Aldrich, St. Louis, MO, USA |
|--|-----------------------------------|

## 2.11 Readymade Solutions/Buffers

Table 10: Name and source of readymade solutions/buffers used in this work

| <b>Solution/buffer</b>                                  | <b>Source</b>  |
|---|--|
| 2x Rapid Ligation buffer                                | Promega Corporation, Madison, WI, USA                  |
| 5x Reaction buffer for RevertAid™ Reverse Transcriptase | (Fermentas) Thermo Fisher Scientific, Waltham, MA, USA |
| Agarose (Biozym LE)                                     | Biozym Scientific GmbH, Hessisch Oldendorf, Germany    |

## 2.13 Cell Culture Mediums and Supplements

Table 12: Type and source of cell culture media and supplements used in this work

| Medium/supplement  | Source                              |
|--|-------------------------------------|
| Ascorbic acid, C <sub>6</sub> H <sub>8</sub> O <sub>6</sub> (30 µg/ml)                                     | Cayman Chemical, Ann Arbor, MI, USA |
| Corning <sup>®</sup> Matrigel <sup>®</sup> Growth Factor Reduced (GFR) Basement Membrane Matrix, LDEV-Free | Corning, NY, USA                    |

|   |  |
|---|--|
| Dextran sulphate sodium salt (200 µg/ml)  | Carl Roth GmbH + Co. KG, Karlsruhe, Germany  |
| DMEM/Nutrient Mixture F-12 Ham medium (DMEM/F12)  | Sigma-Aldrich, St. Louis, MO, USA            |
| Dulbecco's modified eagle medium (DMEM) high-glucose medium (4.5 g/l)   | Thermo Fisher Scientific, Waltham, MA, USA   |
| Dulbecco's phosphate-buffered saline (DPBS)   | Sigma-Aldrich, St. Louis, MO, USA            |
| EGMPlus Endothelial Cell Growth Media   | Lonza Group, Ltd., Basel, Switzerland        |
| EGM-Plus SingleQuot Kit: Fetal Bovine Serum (FBS), Hydrocortisone, bovine brain extract (BBE), L-Glutamine, Heparin, Ascorbic acid, recombinant human epidermal growth factor (rhEGF) | Lonza Group, Ltd., Basel, Switzerland        |
| Fetal Calf Serum (FCS)  | Life Technologies, Carlsbad, CA, USA         |
| Geltrex Growth Factor Reduced Basement Membrane Matrix, LDEV-Free   | Thermo Fisher Scientific, Waltham, MA, USA   |
| Geneticin™ Selective Antibiotic (G418 sulphate), C <sub>20</sub> H <sub>4</sub> ON <sub>4</sub> O <sub>10</sub> ·H <sub>2</sub> SO <sub>4</sub>                                       | Thermo Fisher Scientific, Waltham, MA, USA   |
| Gentamicin (5 mg/ml)/Amphotericin (125 µg/ml)   | Thermo Fisher Scientific, Waltham, MA, USA   |
| Gentamycin (5 µg/ml)  | Sigma-Aldrich, St. Louis, MO, USA            |
| Insulin (27 USP-units/mg)   | Thermo Fisher Scientific, Waltham, MA, USA   |
| KnockOut DMEM Medium  | (Gibco) Life Technologies, Carlsbad, CA, USA |
| KnockOut Serum Replacement (5% v/v)   | (Gibco) Life Technologies, Carlsbad, CA, USA |
| L-Glutamine (200 mM)  | Thermo Fisher Scientific, Waltham, MA, USA   |
| Nicotinamide (10 mM)  | Sigma-Aldrich, St. Louis, MO, USA            |
| Non-essential amino acids solution (0.1 mM)   | (Gibco) Life Technologies, Carlsbad, CA, USA |
| OptiMEM™ medium   | Thermo Fisher Scientific, Waltham, MA, USA   |
| Penicillin (10.000 Units/ml) / streptomycin (10 mg/ml)  | Thermo Fisher Scientific, Waltham, MA, USA   |
| Poly-L-Lysine Hydrobromide (0.1 mg/ml)  | Sigma-Aldrich, St. Louis, MO, USA            |
| RPMI medium   | Thermo Fisher Scientific, Waltham, MA, USA   |
| VEGF (50 ng/ml)   | PeptoTech, Hamburg, Germany                  |
| β-Mercaptoethanol (0.1 mM)  | Sigma-Aldrich, St. Louis, MO, USA            |

## 2.14 Consumables

Table 13: Consumables and their commercial sources used in this work

| Consumables   | Source   |
|---|--|
| 0.2 ml Strep-Tactin Sepharose columns   | Iba Life Sciences, Götting, Germany                  |
| 1 ml Strep-Tactin Sepharose columns   | Iba Life Sciences, Götting, Germany                  |
| 12-well/ 24-well ThinCert® Cell Culture Inserts (Transwell filters), 0.4-µm pore size | Greiner Bio-One International, Kremsmünster, Austria |
| 5 ml Strep-Tactin Sepharose column  | Iba Life Sciences, Götting, Germany                  |
| 6/12/24-well cell culture plates  | Greiner Bio-One GmbH, Frickenhausen, Germany         |
| Cell culture dishes 10 cm   | Sarstedt AG & Co., Nümbrecht, Germany                |

|  |  |
|--|--|
| Cell culture flasks T25                                  | Sarstedt AG & Co., Nümbrecht, Germany                    |
| Cell scrapers (blade width 14 mm)                        | TPP Techno Plastic Products AG, Trasadingen, Switzerland |
| Cuvettes   | Sarstedt AG & Co., Nümbrecht, Germany                    |
| Eppendorf tubes 0.5/1.5/2.0 ml                           | Sarstedt AG & Co., Nümbrecht, Germany                    |
| Falcon tubes 15/50 ml                                    | Sarstedt AG & Co., Nümbrecht, Germany                    |
| Flat bottom 96-well assay plates                         | Greiner Bio-One GmbH, Frickenhausen, Germany             |
| Mini cell scrapers (blade width 5 mm)                    | VWR International Germany GmbH, Darmstadt, Germany       |
| NativePAGE™ 4-16% Bis-Tris Protein Gels, 1.0 mm, 10-well | Invitrogen, Thermo Fisher Scientific, Waltham, MA, USA   |
| PCR cups   | Biozym Scientific GmbH, Hessisch Oldendorf, Germany      |
| Petri dishes 10 cm                                       | Sarstedt AG & Co., Nümbrecht, Germany                    |
| Pipette tips 10/100/1000 µl                              | VWR International Germany GmbH, Darmstadt, Germany       |
| Plastic pipettes 5/10/20 ml                              | Sarstedt AG & Co., Nümbrecht, Germany                    |
| Polyvinylidene difluoride (PVDF) membranes               | Merck KGaA, Darmstadt, Germany                           |
| QIAshredder, disposable cell-lysate homogenizers         | Qiagen, Hilden, Germany                                  |
| Sterile filter pipette tips 10/100/1000 µl               | Greiner Bio-One International, Kremsmünster, Austria     |
| Whatman paper 3 mm                                       | Carl Roth GmbH + Co. KG, Karlsruhe, Germany              |

## 2.15 Devices/Tools

Table 14: Name and source of devices/tools used in this work

| Device/tool  | Source  |
|--|---|
| 96-Well Wound maker  | Essen BioScience, Ann Arbor, MI, USA                  |
| Accu-jet Pipette Controller  | Brand, Wertheim, Germany                              |
| Autoclave "Autoklav V-150"   | Systec GmbH, Wettenberg, Germany                      |
| BlueMarine™ 200 Horizontal Submarine Electrophoresis Unit          | SERVA Electrophoresis GmbH, Heidelberg, Germany       |
| Bunsen burner Gasprofi1  | WLD Tec, Göttingen, Germany                           |
| CASY TT Cell Counter   | Innovatis Roche AG, Bielefeld, Germany                |
| Dark Hood DH-40  | Biostep GmbH, Burkhardtsdorf, Germany                 |
| Duomax 1030 Rocking Platform Shaker                                | Heidolph Instruments GmbH & Co.KG, Schwabach, Germany |
| Epithelial Volt/Ohm Meter  | World Precision Instruments GmbH, Berlin, Germany     |
| Eppendorf 5415R (refrigerated centrifuge for Eppendorf cups)       | Eppendorf AG, Hamburg, Germany                        |
| Fine scales "Feinwaage Explorer"                                   | OHAUS, Nänikon, Switzerland                           |
| Ice Machine AF 100   | Scotsman, VerNicht Hills, IL, USA                     |
| Incubator for bacteria 37°C  | Memmert GmbH, Schwabach, Germany                      |
| Incubator Hera Cell 150  | Thermo Fisher Scientific, Waltham, MA, USA            |
| Incubator Hood TH 15 combined with the Bühler Compact Shaker KS 15 | Edmund Bühler GmbH, Bodelshausen, Germany             |
| Leica microscope Type 090-136.001                                  | Leica Microsystems GmbH, Wetzlar, Germany             |
| LI-COR Odyssey Imaging System                                      | LI-COR Biosciences, Lincoln, NE, USA                  |

|  |  |
|--|--|
| Megafuge 1.0R (refrigerated centrifuge for Falcon tubes) | Heraeus Holding GmbH, Hanau, Germany   |
| Microwave KOR-6D07                                       | Daewoo, Seoul, Korea   |
| Milli-Q-Synthesis Water Purification System              | Merck KGaA, Darmstadt, Germany   |

### 3. Methods

#### 3.1 Genomic DNA Isolation and Purification

Total genomic DNA was isolated from cultured cells using the NucleoSpin® Tissue Kit, according to the manufacturer's protocol. Genomic DNA was eluted in 50 µl of Milli-Q H<sub>2</sub>O and the concentration was measured using the NanoDrop® ND1000 Spectrophotometer. Purified genomic DNA was kept at -20°C until further use.

#### 3.2 RNA Isolation and Purification

Total RNA was isolated from cultured cells using the PureLink RNA Micro Kit (Invitrogen), according to the manufacturer's protocol with slight modifications: Wash Buffer I provided by PureLink RNA Micro kit was pre-incubated with RNase-Free DNase set (Qiagen) for 15 min at room temperature (RT) before use according to the manufacturer's protocol. QIAshredder cell-lysate homogeniser (Qiagen) were used in the cell lysing step. RNA was eluted in RNase-free H<sub>2</sub>O and the concentration was measured using the NanoDrop® ND1000 Spectrophotometer. Purified RNA was kept at -80°C until further use.

#### 3.3 cDNA Synthesis by Reverse Transcription of Total RNA

One microgram of purified RNA was mixed with 1 µl of Random Hexamer primers and the final reaction volume was adjusted to 12.5 µl using RNase-free H<sub>2</sub>O. After an initial five-min incubation step at 65°C (Annealing, Table 16), the mixture was placed on ice and 7.5 µl of reaction mix containing reverse transcriptase was added (see Table 17). The reaction was completed in the thermocycler according to the program shown in Table 16.

Table 16: Thermocycler program used for cDNA synthesis

| Reaction Step                        | Temperature | Duration |
|--------------------------------------|-------------|----------|
| Annealing                            | 65°C        | 5 min    |
| cDNA synthesis and heat-inactivation | 25°C        | 10 min   |
|                                      | 42°C        | 60 min   |
|                                      | 70°C        | 10 min   |

Table 17: Reaction mixture for synthesis of cDNA

| Component   | Volume |
|---|--------|
| RNase-free H <sub>2</sub> O                             | 0.5 µl |
| 5x Reaction buffer for RevertAid™ Reverse Transcriptase | 4 µl   |
| dNTPs (1.25 mM)   | 2 µl   |
| RevertAid™ Reverse Transcriptase                        | 1 µl   |

### 3.4 Targeted DNA Amplification by Polymerase Chain Reaction (PCR)

The DNA regions of interest were PCR amplified from cDNA, plasmid or genomic DNA using GoTaq® DNA-Polymerase. PCR reaction mixture and thermocycler program are indicated in Table 18 and Table 19. Annealing temperature and elongation time (1 min/1000 bp) were optimised according to the DNA sequence to be amplified and the primers used (see Table 2 for primer specification).

Table 18: Reaction mixture for PCR

| Component                       | Volume   |
|---------------------------------|----------|
| 5x Green GoTaq® Reaction buffer | 5 µl     |
| Primer Forward (10 µM)          | 1 µl     |
| Primer Reverse (10 µM)          | 1 µl     |
| dNTPs (1.25 mM)                 | 1 µl     |
| DNA (25 µg/µl)                  | 2 µl     |
| GoTaq® DNA-Polymerase           | 0.25 µl  |
| Milli-Q H <sub>2</sub> O        | 14.75 µl |

Table 19: Thermocycler program used for PCR

| Reaction Step        | Temperature | Duration | Cycles |
|----------------------|-------------|----------|--------|
| Initial denaturation | 95°C        | 3 min    | 30     |
| Denaturation         | 94°C        | 30 sec   |        |
| Annealing            | X°C         | 30 sec   |        |
| Elongation           | 72°C        | X min    |        |
| Final Elongation     | 72°C        | 5 min    |        |
| Pause                | 4°C         | -        |        |

### 3.5 Agarose Gel Electrophoresis

PCR products were mixed with 5x DNA-Gel Loading buffer and separated by electrophoresis on 1-2% agarose gel (1% for fragments larger than 1000 bp, 1.5% for fragments between 1000 and 500 bp, 2% for fragments smaller than 1000 bp). The agarose was dissolved in TBE buffer by microwave heating. After cooling the solution to > 45°C, two drops of 0.07% ethidium bromide solution were added and the gels were poured. Electrophoretic separation was performed at 190 V for about 30 min. Amplification products were visualized with an UV transilluminator placed in a dark hood DH-40 (Biostep GmbH, Jahnsdorf, Germany). Gel runs were documented with the software ArgusX1 V4.0.81. For gel purification, DNA fragments of the correct size were excised from the gel (see section 3.6). The GeneRuler™ DNA Ladder Mix served as a size standard.

### 3.6 Purification of PCR Products

PCR products were excised from agarose gels and purified using the NucleoSpin® Gel and PCR Clean-up kit according to the manufacturer's instructions. DNA was eluted in 25 µl of Milli-Q H<sub>2</sub>O and stored at -20°C until further use. DNA concentrations were determined using a NanoDrop® ND1000 Spectrophotometer.

### 3.7 Sanger Sequencing

DNA sequencing was performed using the BigDye® Terminator v1.1, v3.1 Cycle Sequencing Kit. The required reaction mixture components and the thermal cycler program used are depicted in Table 20 and Table 21.

Table 20: Reaction mixture for Sanger sequencing

| Component                               | Volume |
|---|--------|
| BigDye® Terminator Reaction Mix         | 0.8 µl |
| 5x BigDye® Terminator Sequencing buffer | 2 µl   |
| Primer (10 µM)                          | 1 µl   |
| DNA (25 µg/µl)                          | 2 µl   |
| Milli-Q H <sub>2</sub> O                | 4.2 µl |

Table 21: Thermocycler program for Sanger sequencing

| Reaction Step        | Temperature | Duration | Cycles |
|----------------------|-------------|----------|--------|
| Initial denaturation | 94°C        | 3 min    |        |
| Denaturation         | 94°C        | 30 sec   | 27     |
| Annealing            | 55°C        | 30 sec   |        |
| Elongation           | 60°C        | 3 min    |        |
| Final Elongation     | 60°C        | 5 min    |        |
| Pause                | 4°C         | -        |        |

Precipitation of the Sanger sequencing products was conducted by adding 2 µl of 3 M sodium acetate and 25 µl of 100% ethanol to each sample, which was then vortexed and centrifuged (30 min, 4000 rpm, 4°C; Centrifuge Megafuge 1.0R). The supernatant was discarded, and the pellet was washed in 100 µl of 70% ethanol followed by a second centrifugation step (20 min, 4000 rpm, 4°C; Centrifuge Megafuge 1.0R). After removal of the supernatant, the pellet was resuspended in 15 µl of HiDi™ formamide, transferred to a 96-well plate for analysis and subjected to analysis using the Abi3130x1 genetic analyser. ApE-A Plasmid Editor software was used to visualize and investigate the sequences obtained.

### 3.8 Quantitative Real-time PCR

The quantitative real-time PCR (qPCR) reaction was conducted with the Takyon™ Low Rox Probe MasterMix dTTP blue and the KiCqStart® Probe Assay (primers and probes used are given in Table 2), using cDNA as a template. Each reaction was performed in technical triplicates utilizing the QuantStudio™ 5 Real-Time PCR System. Details on reaction composition and PCR conditions are shown in Table 22 and Table 23. Data analysis implied the  $\Delta\Delta C_t$  method for relative quantification<sup>245</sup>.

Table 22: Reaction mixture for qPCR

| Component                                 | Volume   |
|---|----------|
| Takyon™ Low Rox Probe MasterMix dTTP blue | 5 µl     |
| Primer Forward (50 µM)                    | 1 µl     |
| Primer Reverse (50 µM)                    | 1 µl     |
| KiCqStart@Probe                           | 0.125 µl |
| cDNA (20 ng/µl)                           | 2.5 µl   |
| Milli-Q H <sub>2</sub> O                  | 0.375 µl |

Table 23: QuantStudio5 PCR program for qPCR

| Reaction Step             | Temperature | Duration | Cycles |
|---------------------------|-------------|----------|--------|
| Polymerase activation     | 95°C        | 10 min   | 40     |
| Denaturation              | 95°C        | 15 sec   |        |
| Annealing plus elongation | 60°C        | 1 min    |        |

### 3.9 Generation of Expression Vectors Encoding for PAI-1

The full-length coding sequence for PAI-1 (NM\_000602.4) was PCR amplified with oligonucleotides primer pairs PAI-1-EcoRI-F and PAI-1-XhoI-R and cDNA obtained by reverse transcription from ARPE-19 total RNA (see sections 3.2 and 3.3). The primers PAI-1-EcoRI-F and PAI-1-XhoI\_wostop-R were utilized for the amplification of the PAI-1 coding sequence without stop codon for insertion into the PEXPR-IBA103 vector allowing the expression of Strep-tagged PAI-1 (primer sequences given in Table 2). After electrophoresis on a 1% agarose gel, the amplified fragments were extracted from the gel and after purification (see section 3.6) were ligated into a cloning vector.

#### 3.9.1 Ligation into pGEM®-T Vector

Amplified coding sequences for PAI-1 were ligated into the pGEM®-T vector using the ligation mixture shown in Table 24 (vector, ligase and buffer all included in the pGEM®-T vector kit). The ligation mixtures were incubated overnight at 4°C and then introduced into *E. coli* cells by heat-shock transformation.

Table 24: pGEM®-T vector ligation mix

| Component                | Volume |
|--------------------------|--------|
| pGEM®-T vector           | 0.5 µl |
| PCR fragment             | 3 µl   |
| 2x Rapid Ligation buffer | 5 µl   |
| T4 DNA Ligase            | 1 µl   |

#### 3.9.2 Heat-shock Transformation of *E. coli*

Hundred µl of chemically competent *E. coli* DH5α cell suspension was thawed on ice and mixed with 5 µl of ligation reaction product. After 30 min of incubation on ice, the cells were heat shocked for 45 sec at 42°C and placed back on ice for 10 min. After adding 400 µl of SOC medium, the cells were incubated on a thermomixer at 37°C for 45 min under gentle

agitation. Cells were then plated on pre-warmed LB-Agar plates containing 100 µg/ml ampicillin and incubated overnight at 37°C. Individual bacterial clones were picked from the plate with a pipette tip, resuspended in 5 ml LB-medium containing ampicillin (100 µg/ml), and again incubated overnight at 37°C. These cultures were later used for the purification of plasmid DNA from *E. coli* or further inoculations.

As the pGEM®-T vector is applicable for blue/white screening, cells transformed with this vector were cultured on LB-Agar plates (containing 100 µg/ml ampicillin) on which a mixture of 10 µl IPTG and 50 µl X-Gal solutions had been plated before. In this case, only white colonies (containing the DNA insert) were selected for further analysis.

### 3.9.3 Plasmid DNA Purification from *E. coli*

For small-scale isolation of plasmid DNA (e.g., applied for molecular cloning), one *E. coli* clone (picked from an LB-agar plate) or 10 µl of an *E. coli* cell culture were inoculated into 5 ml LB-medium supplemented with 100 µg/ml ampicillin and incubated overnight on a shaker at 37°C. The next day, small-scale isolation of plasmid DNA from the freshly grown *E. coli* cultures was performed using the NucleoSpin® Plasmid Mini kit according to the manufacturer's instructions. The plasmid DNA pellet was eluted in 25 µl of Milli-Q H<sub>2</sub>O and stored at -20°C until further use. DNA concentration was measured using the NanoDrop® ND1000 spectrophotometer.

For transfection-grade plasmid DNA purification, 50 µl of an *E. coli* cell culture were inoculated into 100 ml LB-medium supplemented with 100 µg/ml ampicillin and incubated overnight on a shaker at 37°C. The next day, the NucleoBond® Xtra Midi/Maxi Kit was used to purify plasmid DNA according to the manufacturer's instructions. The plasmid DNA pellet was dissolved in Milli-Q H<sub>2</sub>O under constant gentle agitation for 60 min. To reach a final concentration of 1 µg/ml (measured by the NanoDrop® ND1000 spectrophotometer), the purified DNA was diluted with Milli-Q H<sub>2</sub>O and stored at -20°C until further use.

### 3.9.4 Restriction Digestion and Cloning into Mammalian Expression Vectors

After confirmation of the correct sequence by Sanger sequencing (see 3.7), the PAI-1 coding sequences were transferred from the pGEM®-T cloning vector into the respective expression vectors. To this end, pGEM®-T containing the DNA insert were digested overnight at 37°C with EcoRI-HF and XhoI restriction enzymes in the digestion mixture shown in Table 25.

Table 25: Reaction mix for digestion of pGEM®-T cloning vector

| Component                | Volume          |
|--------------------------|-----------------|
| pGEM®-T                  | 3 µg            |
| EcoRI-HF                 | 1 µl            |
| XhoI                     | 1 µl            |
| Cutsmart buffer          | 1 or 2 µl       |
| Milli-Q H <sub>2</sub> O | ad. 10 or 20 µl |

Using the same enzymes, 0.5 µg of target expression vectors (pcDNA3.1 or pEXPR-IBA103) was digested. After electrophoresis on 1% agarose gel, the digested DNA insert, and expression vectors were purified from the gel and ligated with a 3:1 molar ratio using T4 DNA ligase according to Table 26. Ligations were incubated at 4°C overnight and subsequently transformed into *E. coli* (see 3.9.2).

Table 26: Reaction mix for ligation of inserts into expression vectors

| Component                | Volume    |
|--------------------------|-----------|
| pcDNA3.1 or pEXPR-IBA103 | 10-20 ng  |
| Insert DNA               | 1 µl      |
| 10x T4 DNA Ligase buffer | 1 µl      |
| T4 DNA Ligase            | 1 µl      |
| Milli-Q H <sub>2</sub> O | ad. 10 µl |

After overnight incubation of individual clones, plasmid DNA was isolated from *E. coli* cultures (see section 3.9.3) and expression constructs were verified by Sanger sequencing (3.7). The PAI-1-encoding expression vectors generated were named pcDNA3.1-PAI-1 and pEXPR-IBA103-PAI-1, respectively.

### 3.9.5 Bacterial Glycerol Stocks

The plasmid constructs generated were maintained in bacterial glycerol stocks. *E. coli* cells from 4 ml of fresh culture (cultured overnight as described in 3.9.3) were pelleted by centrifugation (5 min, 1000 rpm, 4°C; Centrifuge Megafuge 1.0R). The cell pellet was then resuspended in 500 µl of LB-medium (without antibiotics) and mixed with 600 µl of 80% sterile glycerol. The stocks were immediately frozen at -80°C. The data sheets of the plasmid constructs and their storage location were entered into the database of the Institute of Human Genetics (University of Regensburg, Germany).

### 3.10 Eukaryotic Cell Culture

Eukaryotic cell lines were maintained at a constant temperature of 37°C, in an atmosphere of 5% CO<sub>2</sub> and were passaged under sterile conditions. Cell status and confluency were checked microscopically each time they were passaged or before being used in the experiments. All cell culture media and supplies (listed in Table 12) were stored at 4°C unless otherwise indicated by the manufacturer and pre-warmed to 37°C before use.

#### 3.10.1 Cultivation of HEK293-EBNA Cells

Human embryonic kidney cells HEK293-EBNA were maintained in 10 cm cell culture dishes in DMEM high-glucose medium containing 10% FCS, 1% penicillin/streptomycin and 1% G418 sulphate. Cells were sub-cultured at a ratio of 1:10 when they reached approximately 90% confluence.

### 3.10.2 Cultivation of HUVEC Cells

Human umbilical vein endothelial cells (HUVECs) were cultivated in T25 cell culture flasks in EGMPlus Endothelial cell growth medium containing EGMPlus SingleQuots kit supplements (but without gentamicin). After reaching approximately 90% confluence, cells were detached with a trypsin-EDTA solution (0.05%) and sub-cultured at a ratio of 1:3.

### 3.10.3 Cultivation of Y79 and WERI-Rb1 Cells

The human retinoblastoma cell lines Y79 and WERI-Rb1 were cultivated in suspension in T25 cell culture flasks in RPMI 1640 medium supplemented with 10% FCS and 1% penicillin/streptomycin. Cells were sub-cultured in a 1:3 ratio when they reached a concentration of  $4-5 \times 10^5$  cells/ml (determined with CASY TT Cell Counter).

### 3.10.4 Cultivation of ARPE-19 Cells

Adult retinal pigment epithelium (ARPE-19) cells were maintained in 10 cm cell culture dishes in DMEM/F12 containing 10% FCS and 1% penicillin/streptomycin solution. After reaching approximately 90% confluence, cells were detached with a trypsin-EDTA solution (0.05%) and sub-cultured at a ratio of 1:3.

### 3.10.5 Cultivation of Human Induced Pluripotent Stem Cells-derived RPE (hiPSC-RPE) Cells

hiPSC-RPE cells were kindly provided by Dr. Karolina Plössl (Institute of Human Genetics, University of Regensburg, Germany). After thawing, cells were cultivated for 2 weeks on 6-well plates coated with Matrigel® GFR in KnockOut DMEM Medium supplied with 2 mM L-Glutamine, 5% (v/v) KnockOut Serum Replacement, 0.1 mM Gibco MEM non-essential amino acids, 5 µg/ml gentamycin, 0.1 mM β-Mercaptoethanol, and 10 mM nicotinamide. After 2 weeks, cells were detached with TrypLE, passaged in a 6-well plate at a 1:6 ratio, and cultivated for another 2 weeks before seeding onto 12-well Transwell filters (coated with Matrigel® GFR) in 1:12 ratio. Unless stated otherwise, cells were maintained on Transwell filters for 6 weeks to allow polarized growth, with a change of culture medium every two days. Cells were used in the experiments during weeks 6-8.

### 3.10.6 Investigations on the Differentiation State of hiPSC-RPE Cells

Characterization of hiPSC-RPE cells during sub-cultivation included monitoring the peculiar RPE cobblestone cell morphology, RPE specific gene expression, and correct localization of RPE-specific markers, as well as integrity and permeability of the cell monolayer.

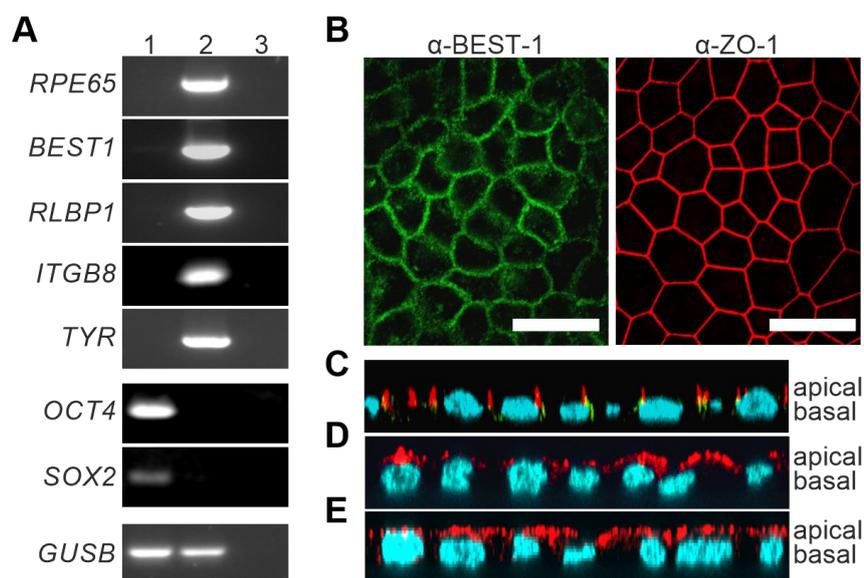

#### 3.10.6.1 Investigating RPE Specific Gene Expression

To investigate the degree of RPE differentiation, expression of the RPE markers *RPE65*, *BEST1*, *RLBP1*, and *ITGB8*, the melanogenesis marker *TYR*, and stem cell markers *OCT4*

and *SOX2* was analysed *via* reverse transcription and targeted PCR amplification of total RNA (as described in paragraph 3.3 and 3.4 with primers given in Table 2) derived from hiPSC-RPE cells in comparison to RNA from undifferentiated hiPSCs. PCR products were separated electrophoretically on 2% agarose gel and visualized with an UV transilluminator placed in a dark hood DH-40 (Biostep GmbH, Jahnsdorf, Germany). Analysis of *GUSB* expression served as housekeeper (**Figure 6A**).

### 3.10.6.2 Immunofluorescence Staining of RPE Cellular Markers

hiPSC-RPE cells on Transwell filters were fixed with 2% PFA solution (Table 11) for 10 min followed by three washing steps for 5 min with DPBS. Upon blocking in blocking solution (Table 11) for 30 min at RT, filters were incubated with primary antibodies (anti-BEST1, anti-ATP1A1, anti-ATP1B1, anti-ZO-1, for antibody solution see Table 11) at 4°C overnight. After three washing steps with DPBS, cells were incubated in fluorescently labelled secondary antibodies (for antibody solution see Table 11) for 1 h at RT. After three washing steps, filters were mounted onto microscope slides using Dako Fluorescence Mounting Medium. All filters were counterstained with DAPI for visualization of cell nuclei. Confocal microscopy (**Figure 6 B**) and vertical z-projection (**Figure 6 C, D, E**) verified the expression and correct (basolateral) localization of the RPE-specific marker Bestrophin-1 (BEST1), the apical polarity of sodium/potassium-transporting ATPase subunit  $\alpha$ -1 (ATP1A1) and  $\beta$ -1 (ATP1B1), and the formation of *zonula occludens* (ZO).

**Figure 6: Profiling of hiPSC-RPE cells.**

(A) Expression of mature RPE genes *RPE65*, *BEST1*, *RLBP1*, and *ITGB8*, the melanogenesis marker *TYR* and stem cell markers *OCT4* and *SOX2* in hiPSCs (lane 1) and hiPSC-RPE (lane 2). No RNA was added to the negative control (lane 3). The housekeeping gene *GUSB* was used to control for RNA integrity. (B) Immunofluorescence staining against basolateral/lateral markers BEST1 (green) and zonula occludens 1 (ZO-1, red). Scale bars 20  $\mu$ m. (C) Vertical z-projection after immunofluorescence staining against BEST1 (green), ZO-1 (red), (D) apical markers ATP1A1 (red) and (E) ATP1B1 (red). Nuclei were visualized with DAPI (blue). (Figure modified from Biasella et al., 2020<sup>246</sup>).

### 3.10.6.3 Measurements of Transepithelial Electrical Resistance

Transepithelial electrical resistance (TEER) of hiPSC-RPE monolayer was measured with an epithelial Volt/Ohm ( $\Omega$ ) Meter after 6 weeks of cultivation, according to the manufacturer's instructions. For measurements, the electrodes were sterilized in 70% ethanol for 15 min, rinsed in 150 mM NaCl solution and placed in the respective Transwell filter, with the longer voltage electrode positioned in the lower chamber while the shorter current electrode was placed in the upper chamber. Blank measurements were taken from Matrigel® coated Transwell filters which did not contain any cells. After subtracting the mean of the blank values from the cell monolayer-derived measurements, net values were multiplied with the surface area of the Transwell filter and reported as  $\Omega \times \text{cm}^2$ . A high stable transepithelial resistance of  $>150 \Omega \times \text{cm}^2$  ( $233.3 \pm 53.2 \Omega \times \text{cm}^2$ ) for differentiated hiPSC-RPE cells confirmed the correct integrity and permeability of the hiPSC-RPE monolayer, consistent with the reported net TEER of human RPE *in vivo*, ranging from 150 to 200  $\Omega \times \text{cm}^2$  <sup>247-249</sup>.

### 3.10.7 Cell transfection

#### 3.10.7.1 Transfection of HEK293-EBNA with the Calcium Phosphate Method

For heterologous expression and purification of Strep-tagged vitronectin isoforms (VTN\_rs704:C and VTN\_rs704:T) and Strep-tagged PAI-1, pEXPR-IBA103 vectors containing the respective coding sequences were transfected into HEK293-EBNA cells using the calcium phosphate method <sup>250</sup>. The day before transfection, HEK293-EBNA cells from a confluent 10 cm dish were passaged at a ratio of 1:3 into 10 cm cell culture dish previously coated with poly-L-Lysine. On the day of transfection, cells were incubated with DMEM High Glucose Medium (4.5 g/l) containing 10% FCS, 1% penicillin/streptomycin and 25  $\mu\text{M}$  chloroquine for 1 h at 37°C. Meanwhile, the transfection mixture was prepared according to Table 27 by first mixing the DNA with Milli-Q H<sub>2</sub>O followed by the addition of CaCl<sub>2</sub>. Subsequently, HBS was added to the tube by gently pipetting to the bottom. The two resulting phases were mixed by gently bubbling air droplets into the solution.

Table 27: Composition of the calcium-phosphate transfection mixture

| Component                | Volume/Amount        |
|--------------------------|----------------------|
| Plasmid DNA              | 40 $\mu\text{g/ml}$  |
| Milli-Q H <sub>2</sub> O | ad.438 $\mu\text{l}$ |
| CaCl <sub>2</sub>        | 62 $\mu\text{l}$     |
| 2x HBS                   | 500 $\mu\text{l}$    |

Directly prior to transfection, the medium containing chloroquine was replaced with normal high-glucose DMEM culture medium (4.5 g/l) containing 10% FCS, 1% penicillin/streptomycin and 1% G418 sulphate, and the transfection mixture was added to the cells dropwise. Seven h after transfection, cells were washed once with DPBS and incubated

in FCS-free medium containing 1% penicillin/streptomycin and 1% G418 sulphate for 72 h. Subsequently, the medium containing secreted Strep-tagged proteins was collected, centrifuged to remove cell debris (5 min; 500 rpm; Centrifuge Multifuge 3L-R), and stored at -20°C until further use. Medium harvested from HEK293-EBNA transfected with an empty vector in a procedure identical to that described above served as a negative control.

### 3.10.7.2 Transfection of HEK293-EBNA with Mirus TransIT®-LTI Transfection Reagent

HEK293-EBNA cells were passaged from a 10 cm confluent dish at a ratio of 1:18 into a 6-well plate or at a ratio of 1:40 in a 12-well plate and incubated overnight in high glucose DMEM medium (4.5 g/l) containing 10% FCS, 1% penicillin/streptomycin and 1% G418 sulphate. The transfection was carried out using the TransIT®-LTI transfection reagent according to the manufacturer's instructions. For co-transfection experiments with two plasmids, half of the amount of DNA was used for each plasmid. The transfected cells were incubated in FCS-free medium for 48 or 72 h at 37°C.

### 3.10.7.3 Transfection of ARPE-19 Cells with Lipofectamine™ 3000 Transfection Reagent

ARPE-19 cells were passaged from a 10 cm confluent dish at a ratio of 1:6 into a 6-well plate or at a ratio of 1:12 into a 12-well plate and incubated overnight in DMEM/F12 containing 10% FCS and 1% penicillin/streptomycin. The transfection was carried out following the Lipofectamine™ 3000 Transfection Reagent protocol according to the manufacturer's instructions, with minor changes in the volumes used (see Table 28). The transfected cells were incubated in FCS-free medium for 48 or 72 h at 37°C.

Table 28: Composition of Lipofectamine™ 3000 transfection mixture

| Component           | Volume (per 6-well) | Volume (per 12-well) |
|---------------------|---------------------|----------------------|
| Lipofectamine™ 3000 | 10 µl               | 5 µl                 |
| P3000™ reagent      | 10 µl               | 5 µl                 |
| DNA (1 µg/ml)       | 2.5 µl              | 1.25 µl              |
| Medium              | 250 µl              | 125 µl               |

Unless otherwise indicated, half of the volume of the DNA was used for each plasmid in co-transfection experiments with two plasmids.

### 3.10.8 Isolation of Primary Porcine RPE Cells

Porcine RPE were isolated from fresh pig eyes obtained from a local slaughterhouse as described in <sup>251</sup>, with only minor modifications. Briefly, porcine eyes were opened through an incision along the ora serrata and the vitreous was removed. After incubation in PBS-EDTA (Table 11), the retinas were discarded and the eye cups were incubated again in PBS-EDTA for 45 min, followed by a 35 min incubation in dissociation buffer containing papain (Table

11). Papain activity was stopped by adding 2% FCS in DPBS. RPE cells were dissociated by suction/pipetting up and down with cell culture medium (KnockOut DMEM Medium supplied with 2 mM L-Glutamine, 0.1 mM Gibco MEM Non-essential amino acids, 5 µg/ml gentamycin, 0.1 mM β-Mercaptoethanol, and 10 mM nicotinamide). The cell suspension was centrifuged (5 min, 1000 rpm, Sigma 2-5 centrifuge) and the cells were used in binding assays (see section 3.27) and adhesion experiments (see section 3.31).

### 3.11 Sodium Dodecyl Sulphate-Polyacrylamide Gel Electrophoresis (SDS-PAGE)

#### 3.11.1 Reducing SDS-PAGE

Protein analysis by western blot or Coomassie staining was preceded by reducing SDS-PAGE for mass-based protein separation. Unless otherwise indicated, protein samples were run on gels consisting of a 12.5% acrylamide resolving layer and a 3% acrylamide stacking layer. Using Bio-Rad MiniPROTEAN® equipment, 1.5 mm thick gels were prepared for western blot analysis, and 0.75 mm thick gels were prepared for Coomassie staining, according to Table 29. Prior to gel loading, samples were sonicated (amplitude: 40%; time: 20 sec) and heated in 5x Laemmli buffer at 93°C for 5 min. As a size standard, 5 µl of PageRuler™ Prestained Protein Ladder was loaded onto the gel. The gels were run in SDS buffer at 50 V until the samples entered the resolving gel and then at 150 V for approximately 2 h depending on the size of the proteins to be analysed.

Table 29: Composition of gels used for reducing SDS-PAGE

| Component           | Resolving gel |         | Stacking gel |
|---------------------|---------------|---------|--------------|
|                     | 10%           | 12.5%   | 3%           |
| 1 M Tris/HCl pH 8.8 | 3.83 ml       | 3.83 ml | -            |
| 1M Tris/HCl pH 6.8  | -             | -       | 2.75 ml      |
| dH <sub>2</sub> O   | 3.66 ml       | 3.03 ml | 1.70 ml      |
| Acrylamide (40%)    | 2.5 ml        | 3.13 ml | 0.55 ml      |
| SDS (20%)           | 100 µl        | 100 µl  | 50 µl        |
| APS (10%)           | 100 µl        | 100 µl  | 50 µl        |
| TEMED               | 10 µl         | 10 µl   | 10 µl        |

#### 3.11.2 Non-Reducing SDS-PAGE

For protein separation under non-reducing conditions, samples were run on 1.5-mm thick acrylamide gels consisting of a 7% resolving layer and a 3% stacking layer (see Table 30 for gel composition). Prior to gel loading, samples were heated in 5x Laemmli buffer without β-Mercaptoethanol at 93°C for 5 min. For the analysis of vitronectin multimers (see section 3.22), Colour-coded Pre-stained Protein Marker, High Range was used as size standard (10 µl). Running conditions were identical to those described in 3.11.1.

Table 30: Composition of gels used for non-reducing SDS-PAGE

| Component           | Resolving gel (7%) | Stacking gel (3%) |
|---------------------|--------------------|-------------------|
| 1 M Tris/HCl pH 8.8 | 3.83 ml            | -                 |
| 1M Tris/HCl pH 6.8  | -                  | 2.75 ml           |
| dH <sub>2</sub> O   | 4.420 ml           | 1.70 ml           |
| Acrylamide (40%)    | 1.75 ml            | 0.55 ml           |
| SDS (20%)           | 100 $\mu$ l        | 50 $\mu$ l        |
| APS (10%)           | 100 $\mu$ l        | 50 $\mu$ l        |
| TEMED               | 10 $\mu$ l         | 10 $\mu$ l        |

### 3.12 Western Blot

Following SDS-PAGE, proteins were transferred onto PVDF membranes by semi-dry blotting using the Bio-Rad Transblot transfer system. The membranes were activated in methanol for 30 sec, and then equilibrated for at least 5 min in Towbin transfer buffer. Similarly, two 3 mm Whatman filter papers and the SDS gel were equilibrated in Towbin transfer buffer. The gel and blotting membranes were assembled in a sandwich along with the filter papers. Protein transfer from the gels onto the membranes was performed at 24 V for 40 min using the Trans-Blot® Turbo™ Transfer System.

After blotting, the membranes were immersed in blocking solution for 1 h at RT and then incubated with primary antibodies in primary antibody solution (see Table 11) overnight at 4°C. Prior to incubation with secondary antibodies, the membranes were washed three times for 5 min in TBS-T at RT. Incubation with the secondary antibodies in secondary antibody solutions (see Table 11) was performed at RT for 1 h, followed by washing of the membranes (3x 5 min in TBS-T). Proteins were visualised by chemiluminescence using Clarity™ ECL Western Blotting Substrate (Bio-Rad) according to the manufacturer's instructions using an Odyssey FC imager. For protein targets showing only weak signals, Clarity Max™ Western Blotting substrate was used to increase signal intensity.

### 3.13 Coomassie Blue Staining

Coomassie blue staining of proteins on SDS gels was applied directly after SDS-PAGE. The gels were immersed in Coomassie staining solution for 1 h and then in Coomassie de-staining solution until the distinct protein species were visible. De-staining solution was replaced by fresh de-staining solution after 1 and 3 h, respectively. The staining and de-staining procedures were carried out at RT under gentle agitation on a shaker.

### 3.14 Blue Native PAGE

For analysis of protein complexes stabilized by non-covalent bonds, samples were separated under native conditions by Blue Native PAGE. Samples were run on pre-cast 4-16% NativePAGE™ Bis-Tris gels at 4°C, according to the manufacturer's instructions. Proteins

were transferred onto PVDF membranes by wet electroblotting overnight using the Bio-Rad Mini Trans-Blot® cell. NuPAGE™ transfer buffer was used according to the manufacturer's instructions. Proteins transferred to PVDF membranes were subjected to western blot analysis.

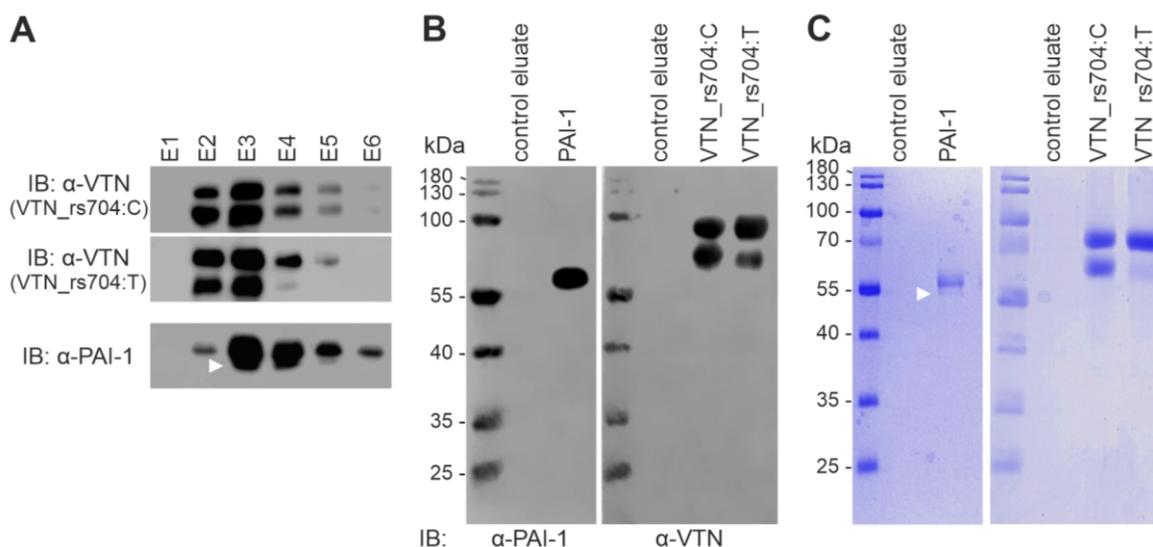

### 3.15 Purification of Recombinant Proteins

Vitronectin (NP\_000629.3) isoforms (VTN\_rs704:C and VTN\_rs704:T) and PAI-1 (NP\_000593.1) were purified in their respective Strep-tagged forms from the culture medium of transiently transfected HEK293-EBNA cells by affinity chromatography. Purification was performed using the Twin-Strep Purification Kit at 4°C with pre-cooled buffers, according to the IBA Life Sciences short purification protocol. Column specifications and buffer volumes used for the purification of VTN\_rs704:C, VTN\_rs704:T, or PAI-1 are shown in Table 31. Ten µl of all six elution fractions was subjected to western blot analyses using antibodies against vitronectin or PAI-1. The three fractions with the highest content of the respective eluted proteins (E2+E3+E4 for VTN\_rs704:C and VTN\_rs704:T, E3+E4+E5 for PAI-1; **Figure 7A**) were combined. Protein purification was controlled in the combined fractions, using western blot analysis (**Figure 7B**) and Coomassie blue staining (**Figure 7C**). Strep-tagged PAI-1 was recognised as a major species of molecular weight slightly above 55 kDa (50-54 kDa for glycosylated PAI-1, as previously reported <sup>252,253</sup>, plus 5.1 kDa for the Strep-tag), with an additional smaller molecular weight species occasionally appearing <sup>254,255</sup>, labelled by white arrows in **Figure 7A, C**. Purified Strep-tagged VTN\_rs704:C and VTN\_rs704:T showed molecular weights of about 80 kDa (75 kDa for the uncleaved vitronectin isoform, plus 5.8 kDa for the Strep-tag) and 65 kDa for the cleaved vitronectin isoform (untagged after cleavage of the 10 kDa C-terminal vitronectin fragment which is fused to the Strep-tag and undetectable with the applied antibody). Aliquoted in 100 µl fractions, the purified proteins were stored at -20°C.

Table 31: Applied affinity chromatography columns and volumes of buffers used for purification of Strep-tagged proteins

|                                    | Gravity flow Strep Tactin Superflow® column capacity | Culture medium applied | Strep-Tactin® wash buffer | Strep-Tactin® elution buffer |
|------------------------------------|--|------------------------|---------------------------|------------------------------|
| <b>Purification of vitronectin</b> | 1 ml   | 70-100 ml              | 5x 1 ml                   | 6x 0.5 ml                    |
| <b>Purification of PAI-1</b>       | 5 ml   | 300-500 ml             | 5x 5 ml                   | 6x 2.5 ml                    |

The culture medium from HEK293-EBNA cells transfected with an empty vector (pEXPR-IBA103) was subjected to the identical purification procedure. The obtained eluates (“control eluate”) served as negative control in experiments conducted with the purified proteins.

**Figure 7: Purification of Strep-tagged VTN\_rs704:C, VTN\_rs704:T and PAI-1.**

The six elution fractions (E1 to E6) collected during purification were subjected to SDS-PAGE and analysed *via* (A) immunoblot (IB) using antibodies against vitronectin ( $\alpha$ -VTN) and PAI-1 ( $\alpha$ -PAI-1). The most concentrated fractions were pooled and used in the experiments. (B) IB analysis and (C) Coomassie blue staining of pooled eluates. Eluates obtained from culture medium of HEK293-EBNA transfected with empty pEXPR-IBA103 vector and subjected to the same purification procedure served as a control (control eluate). White arrowheads indicate the additional smaller PAI-1 band, occasionally observed after expression/purification of PAI-1 (as also described in <sup>254,255</sup>).

### 3.16 Measurement of Protein Concentration

Protein concentration was measured according to Bradford's method <sup>256</sup> using the Roti®-Quant reagent and bovine serum albumin (BSA) as a standard. Eight hundred  $\mu$ l of Milli-Q H<sub>2</sub>O was mixed with 200  $\mu$ l of Roti®-Quant, and 5-15  $\mu$ l of the protein sample to be measured was added. After 20 min of incubation at RT, the absorbance at 595 nm was measured with the Ultrospec 2100 pro UV/Visible spectrophotometer. The protein concentration was determined with the help of a titration curve from known concentrations of BSA.

The concentration of vitronectin isoforms (VTN\_rs704:C and VTN\_rs704:T) were additionally investigated by semi-quantitative western blot analysis comparing signal intensities of the purified vitronectin isoforms to signal intensities of a commercially available recombinant vitronectin protein (10424-H08H; Sino Biological) loaded in different concentrations.

For dilution or adjustment of purified VTN\_rs704:C, VTN\_rs704:T and PAI-1 to the concentrations given in the respective experiments, the Strep-Tactin® elution buffer was used.

### 3.17 Partial Rapid Proteolysis Assay

Fifteen  $\mu$ l of 1.5  $\mu$ g/ml purified recombinant vitronectin (isoforms) were pre-incubated at 37°C or 42°C or kept on ice without pre-incubation. After 10 min, 5  $\mu$ l of 50  $\mu$ g/ml TPCK-trypsin in Tris-buffered saline was added to the samples, and the mixtures were kept at 37°C for further 5 min. As a control, 15  $\mu$ l of purified protein without or with the same pre-incubation

steps were mixed with 5 µl of only Tris-buffered saline and subjected to the 5 min incubation step at 37°C. The mixtures were finally boiled with 5 µl 5x Laemmli buffer for 5 min at 95°C, subjected to SDS-PAGE in 10% acrylamide gels, and analysed by western blot.

### 3.18 Analysis of Endogenous Vitronectin Expression in Different Cell Lines

Endogenous vitronectin expression was tested in ARPE-19, hiPSC-RPE, Y79, WERI-Rb1, HUVEC, and HEK293-EBNA cells.

#### 3.18.1 Vitronectin mRNA Expression

For RNA isolation, half of the ARPE-19 cells grown to confluence in a 10 cm dish, a third of the HEK293-EBNA cells from a confluent 10 cm dish, hiPSC-RPE cells from 4 Transwell filters and Y79, WERI-Rb1, as well as HUVECs from a fully grown T25 flask were used. After reverse transcription of the isolated total RNA (see sections 3.2 and 3.3), the *VTN* coding sequence was amplified by PCR with the oligonucleotide primers given in Table 2. Amplification of the *GUSB* coding sequence served as control. The PCR products were electrophoresed on 1.7% agarose and visualised with an UV transilluminator placed in a dark hood DH-40 (Biostep GmbH, Jahnsdorf, Germany).

#### 3.18.2 Vitronectin Protein Expression

The preparation of cell lysates from cultured ARPE-19, hiPSC-RPE, Y79, WERI-Rb1, HUVEC and HEK293-EBNA cells and the determination of the respective total protein concentrations *via* the Bradford method<sup>256</sup> was performed by medical doctoral student Martin Zankel. Forty µg of total protein was used for all cell lines. Samples were mixed with 5x Laemmli buffer and heated at 95°C for 5 min. Proteins were then separated by SDS-PAGE as outlined in section 3.11.1 and subjected to western blot analysis (see section 3.12).

### 3.19 Analysis of rs704 Allele-specific mRNA Expression in hiPSC-RPE and Human Neural Retinal Samples

Vitronectin mRNA expression was investigated *via* analysis of sequence electropherogram of allele-specific transcripts in hiPSC-RPE cells and human neural retina samples (Institute of Human Genetics, University of Regensburg, Germany), which were heterozygous for rs704. Genomic DNA and RNA were isolated from hiPSC-RPE cells and human neural retina samples, following the procedures described in sections 3.1 and 3.2. The RNA was then transcribed into cDNA (see 3.3). The cDNA sequence regions comprising rs704 were amplified by PCR (see section 3.4) with primers *VTN\_SeqInt2\_F* and *hVTN\_Ex7-R* given in Table 2. Successful amplification was verified by electrophoresis of the PCR products on 1.5% agarose gels (see section 3.5). Excess primers and dNTPs were removed by treatment with exonuclease I and Antarctic phosphatase for 15 min at 37°C, followed by further 15 min at 80°C according to Table 32.

Table 32: Reaction mix for PCR products treatment with Exonuclease and Antarctic phosphatase

| Component                | Volume        |
|--------------------------|---------------|
| Exonuclease              | 0.1 $\mu$ l   |
| Antarctic phosphatase    | 0.25 $\mu$ l  |
| PCR product              | 1 $\mu$ l     |
| Milli-Q H <sub>2</sub> O | ad. 5 $\mu$ l |

Sanger sequencing was performed with sequencing primer hVTN\_Ex7-R given in Table 2, according to the protocol described in section 3.7. Sequence electropherograms were visualised with the ApE-A Plasmid Editor software.

### 3.20 Analysis of rs704 Allele-specific Heterologous Vitronectin Protein Expression and Processing

HEK293-EBNA and ARPE-19 cells were co-transfected in 12-well plates with pcDNA3.1-GFP in combination with empty pcDNA3.1, pcDNA3.1-VTN\_rs704:C, or pcDNA3.1-VTN\_rs704:T, respectively, according to the transfection methods described in sections 3.10.7.2 and 3.10.7.3. After 48 and 72 h, the medium (1 ml) was collected and centrifuged to remove cellular debris (5 min, 800 rpm, 4°C; Centrifuge Eppendorf 5415R). Cells were scraped in 300  $\mu$ l DPBS and pelleted by centrifugation (5 min, 4500 rpm, 4°C; Centrifuge Eppendorf 5415R). After a second wash with 300  $\mu$ l DPBS, the cell pellet was resuspended in 100  $\mu$ l of DPBS. Cells and supernatant were subjected to SDS-PAGE (see 3.11.1) and western blot analysis (see 3.12) with antibodies against vitronectin, GFP and ACTB.

### 3.21 Analysis of Endogenous Proteolytic Cleavage of Vitronectin

HEK293-EBNA cells were co-transfected in 6-well plates with pcDNA3.1-PAI-1 in combination with empty pcDNA3.1, pcDNA3.1-VTN\_rs704:C, or pcDNA3.1-VTN\_rs704:T, respectively, according to the transfection method described in section 3.10.7.2. Co-expression of PAI-1, a known plasmin inhibitor, was performed to prevent endogenous plasmin-mediated cleavage of vitronectin on the carboxy-terminal side of R380<sup>257,258</sup> in order to better visualize the different accessibility of VTN\_rs704:C and VTN\_rs704:T towards the endogenous intracellular furin protease, which mediates cleavage on the carboxy-terminal side of R398<sup>204</sup>, susceptible to rs704<sup>237</sup>. After 48 h, cells were resuspended in their medium and pelleted by centrifugation (5 min, 800 rpm, 4°C; Centrifuge Eppendorf 5415R). The supernatant (culture medium) was collected, and the cell pellets were washed in 300  $\mu$ l DPBS, pelleted (5 min, 4500 rpm, 4°C; Centrifuge Eppendorf 5415R) and finally resuspended in 200  $\mu$ l DPBS. Cells and supernatant were subjected to SDS-PAGE (see 3.11.) and western blot analysis (see 3.12) with antibodies against vitronectin, PAI-1 and ACTB.

### **3.22 Analysis of rs704-dependent Vitronectin Multimerization**

Twenty  $\mu\text{l}$  of purified recombinant VTN\_rs704:C and VTN\_rs704:T were subjected to non-reducing SDS-PAGE (see section 3.11.2) at a concentration of 10 ng/ml, and to BN-PAGE (see section 3.14) at a concentration of 85 ng/ $\mu\text{l}$ . Subsequently, western blot analyses (see 3.12) with antibodies against vitronectin were performed.

### **3.23 Analysis of rs704-dependent Vitronectin Binding to Immobilized PAI-1**

The binding of VTN\_rs704:C and VTN\_rs704:T to PAI-1 was investigated by affinity chromatography of vitronectin to immobilized PAI-1. Seventy-five  $\mu\text{l}$  of purified recombinant Strep-tagged PAI-1 (100  $\mu\text{g}/\text{ml}$ ) was loaded onto gravity flow columns (0.2 ml Strep-Tactin Sepharose columns) pre-equilibrated with 200  $\mu\text{l}$  of Strep-Tactin® wash buffer (buffer W) and incubated for 15 min. After washing the columns five times with 200  $\mu\text{l}$  buffer W, 2.0 ml of culture medium containing untagged VTN\_rs704:C or VTN\_rs704:T (FCS-free medium of HEK293-EBNA cells transfected with pcDNA3.1-VTN\_rs704:C or pcDNA3.1-VTN\_rs704:T, adjusted for vitronectin concentrations) was loaded onto the columns and incubated for 1 h. In the medium, the concentration of untagged recombinant vitronectin was estimated to be approximately 5  $\mu\text{g}/\text{ml}$  by comparative western blot analysis with a commercially available recombinant vitronectin protein (10424-H08H; Sino Biological). After six washing steps with 200  $\mu\text{l}$  buffer W, proteins were eluted five times with 100  $\mu\text{l}$  of Strep-Tactin® elution buffer (buffer E). To investigate putative non-specific binding of vitronectin to the column material, the VTN\_rs704:C- or VTN\_rs704:T-containing medium was loaded onto PAI-1-free columns in otherwise identical affinity chromatography experimental procedures. The pooled elution fractions were analysed via SDS-PAGE (see 3.11.1) and western blot analysis (see 3.12) with antibodies against vitronectin and PAI-1.

### **3.24 Analysis of Endogenous PAI-1 Protein Expression in Cultured Endothelial and RPE cells**

ARPE-19 and HUVEC cells were passaged from a 10 cm confluent dish and a T25 confluent flask, respectively, at a 1:6 ratio onto 6-well plates and incubated for 24 h. After 24 h incubation, the culture medium was replaced by FCS-free culture medium, upon washing the cells once with 1 ml DPBS. After further 72 h of incubation, the culture medium was collected and the cells were scraped in 300  $\mu\text{l}$  DPBS, pelleted (5 min, 4500 rpm, 4°C; Eppendorf 5415R centrifuge) and finally resuspended in 200  $\mu\text{l}$  DPBS. Cell pellet samples were sonicated (amplitude: 40%; time: 20 sec) and the total protein concentration of the obtained cell lysates was measured by the Bradford method <sup>256</sup>, using Roti®-Quant reagent and BSA as a standard. Ten  $\mu\text{g}$  of total protein was used for each cell line and, together with the culture medium samples, subjected to SDS-PAGE (see section 3.11.1) and western blot analysis (see section 3.12). As a positive control, 2  $\mu\text{g}/\text{ml}$  of recombinant PAI-1 purified from

the culture medium of HEK293-EBNA cells transfected with the expression vector for PAI-1 was loaded.

### **3.25 Analysis of Endothelial PAI-1 Expression and Deposition After Exposure to Recombinant VTN\_rs704:C and VTN\_rs704:T**

Confluent HUVECs (passages 3-4) from a T-25 flask were passaged onto 24-well plates at a density of  $5.0 \times 10^5$  cells/well for subsequent mRNA analysis and  $3.75 \times 10^5$  cells/well for subsequent protein analysis (cell concentration determined with CASY TT Cell Counter). After seeding, 20  $\mu\text{g/ml}$  of VTN\_rs704:C or VTN\_rs704:T, or an equal volume of control eluate was added to the cells, which were then incubated at 37°C in FCS-free HUVEC culture medium. After 24 h, mRNA expression of *PAI-1* and *HPRT* (housekeeping gene) was followed by qPCR with oligonucleotide primers and probes given in Table 2.

For protein analysis, the medium was removed after 24 h, and cells were gently scraped off with a mini cell scraper in 300  $\mu\text{l}$  DPBS. After centrifugation (5 min, 4500 rpm, Sigma 2-5 centrifuge), the cell pellet was resuspended in 50  $\mu\text{l}$  DPBS. To collect the ECM deposited by HUVECs, 200  $\mu\text{l}$  of decellularization buffer (see Table 11) was added to the wells for 5 min at RT to lyse any remaining cells. After washing five times with DPBS, 40  $\mu\text{l}$  of hot Laemmli buffer (95°C) mixed with 100mM dithiothreitol (DTT) was pipetted onto the wells and the ECM was scraped into this buffer. The collected cells and ECM samples were subjected to SDS-PAGE (see 3.11.1) followed by western blot analysis (see 3.12) with antibodies against vitronectin, PAI-1 and ACTB.

### **3.26 Analysis of ECM Deposition by ARPE-19 Cells Heterologously Expressing VTN\_rs704:C and VTN\_rs704:T**

ARPE-19 cells grown on a 6-well plate were co-transfected with pcDNA3.1-GFP and pcDNA3.1, pcDNA3.1\_VTN\_rs704:C, or pcDNA3.1\_VTN\_rs704:T using Lipofectamine™ 3000 Transfection Reagent, as described in section 3.10.7.3. After 24 h, GFP fluorescence was assessed as a marker for transfection efficiency using Nikon Eclipse microscope. Transfected ARPE-19 cells were enzymatically dissociated from the cell culture plate with trypsin–EDTA and  $4 \times 10^5$  cells (determined with CASY TT Cell Counter) were seeded onto 12-well Transwell filters (0.4- $\mu\text{m}$  pore size) in DMEM/HamsF12 containing 10% FCS and 1 % penicillin/streptomycin. After 24 h, the medium was changed to FCS-free medium containing 1% penicillin/streptomycin and supplemented with 200  $\mu\text{g/ml}$  dextran sulphate and 30  $\mu\text{g/ml}$  ascorbic acid, according to <sup>259</sup>. Confluent ARPE-19 monolayers were cultured in this medium for 4 or 8 weeks with media changes three times per week. After the incubation period, cells were removed from the filter by decellularization for 5 min at 37°C with 500  $\mu\text{l}$  (upper chamber) and 1.5 ml (lower chamber) decellularization buffer (see Table 11). After decellularization, filters were washed five times with DPBS (500  $\mu\text{l}$  on the upper chamber and

1.5 ml on lower chamber) and the deposited ECM was fixed for subsequent immunofluorescence analyses, with the procedure described in paragraph 3.10.6.2. Immunostaining was performed with one quarter filter per staining experiment. Pictures were taken with a confocal laser scanning microscope. Signal intensity and average cluster size were measured using ImageJ.

### **3.27 Cell Membrane Binding assay**

The binding of VTN\_rs704:C and VTN\_rs704:T to ARPE-19, hiPSC-RPE, porcine RPE, Y79, and HUVECs was tested by suspending cell pellets (Y79: cells from one or two fully grown T25 flasks, respectively; ARPE-19: cells from one fully grown 10 cm dish; hiPSC-RPE: cells from six 12-well filters; porcine RPE cells: RPE cells from one eye) in 600  $\mu$ L of DPBS. The 600  $\mu$ l suspensions were split into three 200  $\mu$ l fractions which were centrifuged (5 min, 4500 rpm, 4°C; Eppendorf 5415R centrifuge). The three pellets were resuspended in 1 ml of vitronectin-containing medium from HEK293-EBNA cells previously transfected with pcDNA3.1-VTN\_rs704:C or pcDNA3.1-VTN\_rs704:T, or in 1 ml of medium from cells transfected with an empty vector. After 1 h incubation at 37°C under constant shaking (400 rpm), cells were washed three times with 1 ml DPBS (followed by centrifugation for 5 min, 4500 rpm, 4°C; Eppendorf 5415R centrifuge). The pellet resuspended in 200  $\mu$ l PBS was subjected to SDS-PAGE (3.11.1) and western blot analysis (3.12) with antibodies against vitronectin and ACTB.

### **3.28 Endothelial Cell Migration (“Scratch-Wound”) Assay**

HUVEC migration was determined in the scratch-wound test, as described in <sup>260</sup>, with slight modifications: HUVECs were passed from a confluent T25 flask at a ratio of 1:35 into a flat-bottom 96-well plate and incubated in HUVEC cultured medium with EGMPlus SingleQuotes supplements. After 24 h, monolayers of confluent cells were scratched using a Wound Maker. Cell debris was removed by washing with DPBS, and injured monolayers were incubated in 100  $\mu$ l EGMPlus Endothelial Cell Growth Media with EGMPlus SingleQuotes supplements except FCS and gentamycin, 50 ng/ml VEGF and 20  $\mu$ g/ml purified recombinant vitronectin (VTN\_rs704:C or VTN\_rs704:T) or equal volumes of control eluate. Minimum four pseudo replicates (individually treated wells) per treatment were performed for each independent replicate. After 0 and 14 h, images of each well were captured at 4x magnification with a Nikon Eclipse microscope. Scratch areas were determined using an ImageJ script for automatic quantification of HUVEC migration kindly provided by Dr. Christina Kiel (Institute of Human Genetics, University of Regensburg, Germany). Cell migration capacity was defined as the percentage area closed after 14 h of incubation.

### 3.29 Enzymatic PAI-1 Activity Assay

The effect of vitronectin isoforms on PAI-1 activity was followed by incubating 7.5 µg/ml of purified recombinant PAI-1 with 7.5 µg/ml of purified recombinant VTN\_rs704:C, VTN\_rs704:T, or control eluate for 7 h at 37°C. After 0, 1, 2, 3, 4, 5, and 7 h, or after 0 and 72 h, 10 µl of the assay mixture were removed and subjected to the CHEMICON PAI Activity Assay Kit (Sigma-Aldrich), according to the manufacturer's protocol. In this assay, the ability of PAI-1 to inhibit its physiological ligand uPA is assessed colorimetrically by quantifying a chromogenic substrate, which is cleaved by active uPA. Specifically, the vitronectin/control eluate and samples containing PAI-1 were first incubated with uPA for 30 min at 37°C, followed by the chromogenic enzymatic reaction for 2 h at 37°C. Subsequently, the absorbance of the chromogenic substrate was measured at 405 nm using a Spark multimode microplate reader.

### 3.30 Endothelial Tube Formation Assay

Endothelial tube formation in response to vitronectin exposure was examined in HUVECs as described in <sup>261</sup>, with minor modifications.  $8.5 \times 10^3$  HUVECs/well were seeded onto a flat-bottom 96-well plate coated with 37.5 µL Geltrex LDEV-Free Reduced Growth Factor Basement Membrane Matrix. Cells were then cultured in 100 µl HUVEC culture medium containing 1/3 EGMPlus SingleQuots supplements without gentamycin, 50 ng/ml VEGF, and 5 µg/ml purified recombinant VTN\_rs704:C or VTN\_rs704:T, or equal volumes of control eluate. Minimum three pseudo replicates (individually treated wells) per each treatment were included in one independent replicate. After 16 h, images from each well were captured at 4x magnification with a Nikon Eclipse microscope. Cumulative tube length was quantified using the Angiogenesis Analyzer in ImageJ as described <sup>262</sup>.

### 3.31 Adhesion Assay

VTN\_rs704:C and VTN\_rs704:T were compared in their capacity to mediate adhesion of hiPSC-RPE, porcine RPE and HUVEC cells. Prior to the assay, cell suspensions were prepared as follows: hiPSC-RPE cells were dissociated from a 12-well Transwell filter using TrypLE for 40 min at 37°C and resuspended in 600 µl of serum-free culture medium. Porcine RPE cells were isolated from a pig eye (see section 3.10.8) and resuspended in 600 µl of serum-free medium. HUVECs from a T25 cell culture flask were resuspended in 1.2 ml of FCS-free culture medium.

#### 3.31.1 Adhesion Assay with Purified Recombinant Vitronectin

Hundred µl of hiPSC-RPE, porcine RPE or HUVEC cell suspension was mixed with 1.5 µg/ml of purified recombinant VTN\_rs704:C or VTN\_rs704:T or equal volumes of control eluate and transferred to a flat-bottom 96-well plate. Cells were then incubated at 37°C for a period of 24

h for hiPSC-RPE, 18 h for porcine RPE cells and 20 min for HUVECs. After incubation, the medium was discarded, and hiPSC-RPE and HUVEC cells were incubated with Hoechst 33342 (1:1000 diluted in DPBS, 100  $\mu$ l per well) for 10 min at RT. After staining, the cells were washed three times for 5 min each with 100  $\mu$ l DPBS. Fluorescence images of adherent cells were taken with a Nikon Eclipse microscope. Cell attachment was quantified by measurement of fluorescence intensity (excitation/emission, 360/490 nm) using a Spark multimode microplate reader. Due to the strong pigmentation of porcine RPE, fluorescent staining with Hoechst 33342 was omitted in the test with this cell type. Instead, images from each 96-well plate were taken at 4 $\times$  magnification with a Nikon Eclipse microscope, and RPE cells were counted using ImageJ.

### **3.31.2 Adhesion Assay on Vitronectin-containing ECM**

Vitronectin-containing ECM was produced by ARPE-19 cells heterologously expressing VTN\_rs704:C or VTN\_rs704:T as described in 3.26, with one modification: After transfection,  $2 \times 10^5$  cells (determined with CASY TT Cell Counter) were seeded onto 24-well Transwell filters. Cultivation for 4 weeks including medium changes and final decellularization was performed as described in 3.26.

After decellularization of Transwell filters with 250  $\mu$ l (upper chamber) and 500  $\mu$ l (lower chamber) decellularization buffer (see Table 11), filters were washed five times with DPBS (250  $\mu$ l on the upper chamber and 500  $\mu$ l on lower chamber). On the decellularized ECM-coated filters, 200  $\mu$ l of hiPSC-RPE, 250  $\mu$ l of porcine RPE, or 200  $\mu$ l of HUVEC cell suspension were seeded. After 40 min (hiPSC-RPE or porcine RPE cells) or 5 min (HUVECs) incubation at 37°C, the culture medium was removed, and cells were incubated with Hoechst 33342 and subsequently washed as described in 3.31.1. Due to the strong pigmentation of porcine RPE, fluorescent staining with Hoechst 33342 was omitted in the test with this cell type. Instead, images from each Transwell filter were taken at 4 $\times$  magnification with a Nikon Eclipse microscope and cells were counted using ImageJ.

### **3.32 MTT Assay**

The effects of VTN\_rs704:C and VTN\_rs704:T on cell viability were explored in ARPE-19 and HUVECs subjected to oxidative stress by applying an MTT assay. ARPE-19 cells and HUVECs were passaged from a confluent 10 cm dish or a T25 flask, respectively, at a ratio of 1:24 into a 24-well plate and incubated in the respective culture medium. After 24 h, monolayers of confluent cells were washed once in 1 ml DPBS and incubated with 250  $\mu$ l of FCS-free culture medium containing 10  $\mu$ g/ml of purified recombinant VTN\_rs704:C or VTN\_rs704:T, or equal volumes of control eluate. The cells were then subjected to 0 mM, 1.5 mM, 3 mM, and 5 mM (ARPE-19) or 0 mM, 0.5 mM, 1 mM, and 3 mM (HUVECs) H<sub>2</sub>O<sub>2</sub> for 2 h at 37°C. After 2 h, the medium was replaced by 250  $\mu$ l fresh FCS-free culture medium

containing 10 µg/ml of purified recombinant VTN\_rs704:C or VTN\_rs704:T, or equal volumes of control eluate. Cells were allowed to recover from H<sub>2</sub>O<sub>2</sub>-induced stress for 18 h before they were subjected to the MTT assay, a colorimetric assay based on the reduction of the yellow tetrazolium salt MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide), to purple formazan crystals by NAD(P)H-dependent oxidoreductase enzymes contained in viable cells<sup>263</sup>. The culture medium was removed, and 1 ml of MTT solution (diluted 1:10 in culture medium) was added to the cells, which were incubated for 30 min at 37°C, until dark blue formazan crystals were visible. After removing the MTT solution, cells were washed in 1 ml DPBS. Finally, 200 µl of 0.1 M HCl in isopropanol was added to each well to dissolve the formazan crystals. After 10 min of gentle agitation, 100 µl of the samples was transferred into flat-bottom 96-well plates and absorbance at 540 nm was measured using a Spark multimode microplate reader.

### **3.33 Autophagy Assay**

The effects of VTN\_rs704:C and VTN\_rs704:T on cellular autophagy were explored in ARPE-19 and HUVECs by monitoring the expression of the autophagy marker LC3. After induction of autophagy by serum (FCS) depletion and H<sub>2</sub>O<sub>2</sub> co-treatment<sup>264,265</sup>, analysis of the content of LC3 protein isoforms (forms I and II, respectively cytosolic and autophagosome-bound isoforms)<sup>266</sup> and their ratio was performed by western blot as previously reported<sup>267</sup>.

#### **3.33.1 Autophagy Assay with ARPE-19 Cells**

ARPE-19 cells were passaged from a 10 cm confluent dish at a ratio of 1:10 into a 12-well plate and incubated overnight in 1 ml culture medium. After washing once with 1 ml pre-warmed DPBS, cells were pre-incubated for 1 h with 1.0 µg/ml VTN\_rs704:C, VTN\_rs704:T or equal volumes of control eluate in 1 ml of FCS-free culture medium. Cells were then treated for 2 h with 1 mM H<sub>2</sub>O<sub>2</sub> in 1 ml fresh FCS-free medium containing 1.0 µg/ml of purified recombinant VTN\_rs704:C or VTN\_rs704:T, or equal volumes of control eluate. After stress induction, cells were scraped into their medium and the cell suspension was centrifuged (5 min, 4500 rpm, 4°C; Eppendorf 5415R centrifuge). After removal of the supernatant, the cells were washed with 1 ml DPBS and centrifuged again as before. The cell pellet was finally resuspended in 120 µl DPBS for SDS-PAGE (3.11.1) and western blot analysis (see 3.12) with antibodies against LC3 and ACTB.

#### **3.33.2 Autophagy Assay with HUVEC Cells**

HUVECs were subjected to the autophagy assay following the procedure described above for ARPE-19 cells, with minor modifications. After being pre-incubated for 1 h with 1.5 µg/ml of purified recombinant VTN\_rs704:C or VTN\_rs704:T, or an equal volume of control eluate, cells were stressed with 1 mM H<sub>2</sub>O<sub>2</sub> for 24 h. Cells were then harvested and washed as

described in the section above, and finally resuspended in 100  $\mu$ l DPBS for SDS-PAGE (3.11.1) and western blot analysis (see 3.12) with antibodies against LC3 and ACTB.

### **3.34 Phospho-ERK Assay**

The effect of VTN\_rs704:C and VTN\_rs704:T on the activation of extracellular signal-regulated kinase (ERK) signalling was studied in ARPE-19 cells and HUVECs by following ERK1/2 phosphorylation *via* western blot analysis.

#### **3.34.1 Phospho-ERK Assay in ARPE-19 Cells**

The phospho-ERK assay was performed with ARPE-19 cells passaged from a 10 cm confluent dish at a ratio of 1:10 into a 12-well plate and incubated overnight in 1 ml culture medium. After washing once with 1 ml pre-warmed DPBS, cells were incubated with 0.5  $\mu$ g/ml of purified recombinant VTN\_rs704:C, VTN\_rs704:T, or equal volumes of control eluate in 1 ml of FCS-free culture medium. After 2 h of incubation, cells were scraped into their medium and the cell suspension was centrifuged (5 min, 4500 rpm, 4°C; Eppendorf 5415R centrifuge). After removal of the supernatant, the cells were washed with 300  $\mu$ l DPBS and centrifuged again as before. The cell pellet was finally resuspended in 120  $\mu$ l DPBS for SDS-PAGE (3.11.1) and western blot analysis (see 3.12) with antibodies against ERK1/2, phospho-ERK1/2 and ACTB.

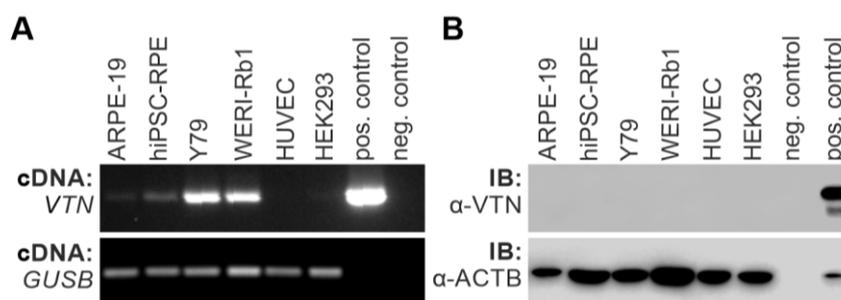

#### **3.34.2 Phospho-ERK Assay in HUVEC Cells**

To follow vitronectin-dependent phosphorylation of ERK1/2 in HUVECs, cells were incubated for 24 h with 1.5  $\mu$ g/ml of purified recombinant VTN\_rs704:C, VTN\_rs704:T, or equal volumes of control eluate. After 24 h of incubation, cells were scraped into their medium and the cell suspension was centrifuged (5 min, 4500 rpm, 4°C; Eppendorf 5415R centrifuge). After removal of the supernatant, the cells were washed with 300  $\mu$ l DPBS and centrifuged again as before. The cell pellet was finally resuspended in 100  $\mu$ l DPBS for SDS-PAGE (3.11.1) and western blot analysis (see 3.12) with antibodies against ERK1/2, phospho-ERK1/2 and ACTB.

## 4. Results

### 4.1 Endogenous Vitronectin Expression in Retinal and Non-retinal Cell Lines

The expression of endogenous vitronectin was analysed in retinal and non-retinal cell lines often used as cellular model systems in *in vitro* analyses of the molecular pathomechanisms of common retinal disorders such as AMD<sup>268-270</sup>. Cell lines included ARPE-19, hiPSC-RPE, Y79, WERI-Rb1, HUVECs, and HEK293-EBNA. Endogenous vitronectin mRNA expression was observed in the two retinoblastoma-derived cell lines Y79 and WERI-Rb1 and, to a weaker extent, in the RPE cell lines ARPE-19 and hiPSC-RPE. No mRNA expression was detected in HEK293-EBNA and HUVEC cells (**Figure 8A**). Western blot analysis failed to detect vitronectin protein in any of the cell lines tested, even after multiple attempts to increase sensitivity (**Figure 8B**).

**Figure 8: Endogenous VTN expression in retinal and non-retinal cell lines.**

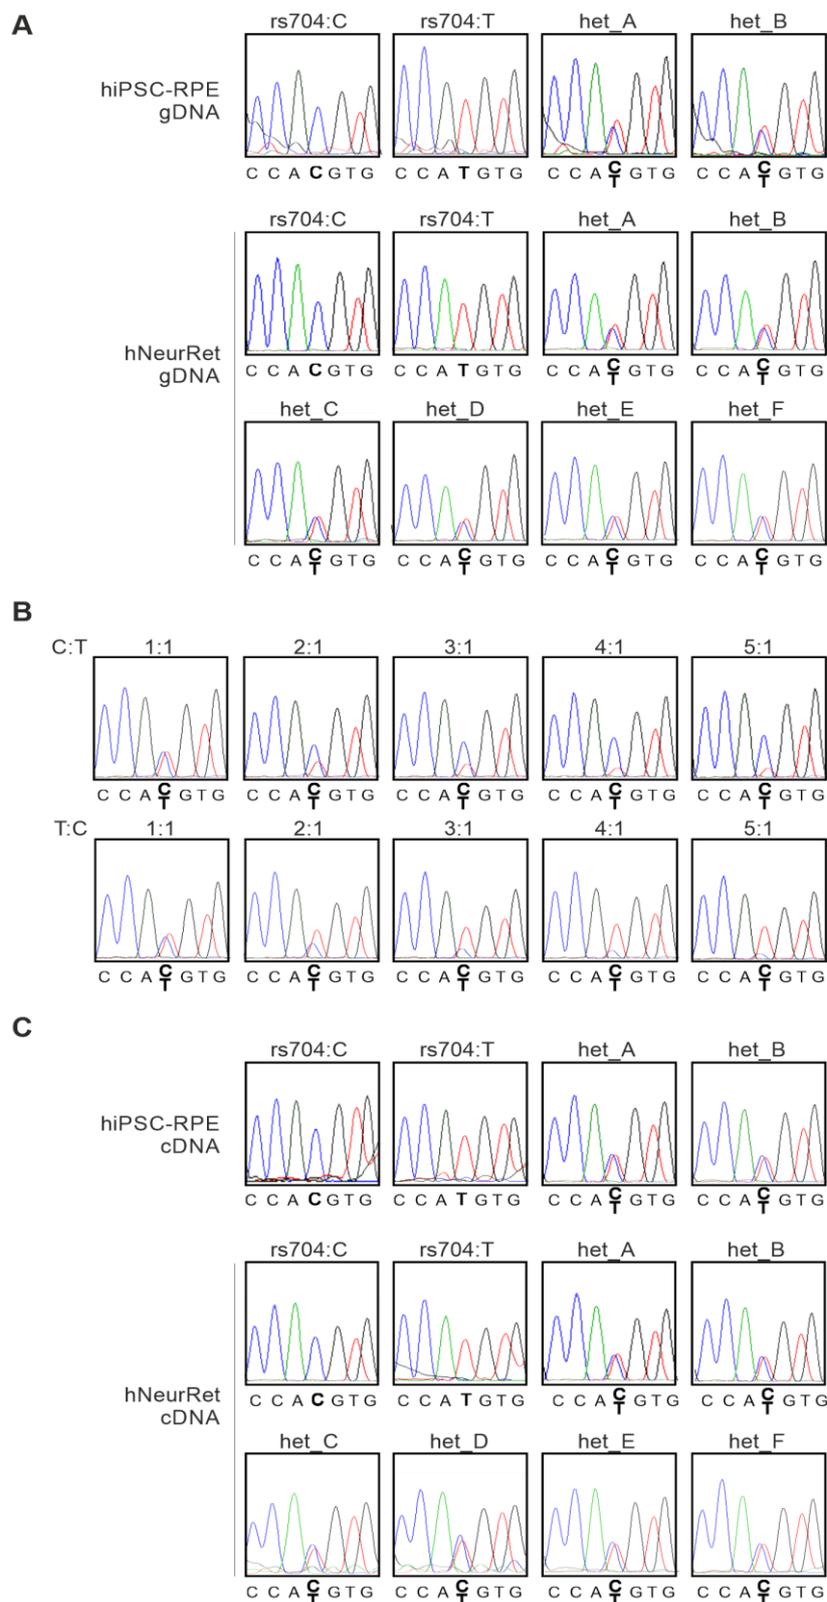

(A) RT-PCR analysis to investigate VTN mRNA expression in ARPE-19, hiPSC-RPE, Y79, WERI-Rb1, HUVEC, and HEK293-EBNA cells. Expression vectors containing cDNA for VTN<sub>rs704:C</sub> served as positive control; no template was added to the negative control. GUSB gene expression was assessed as control for RNA integrity. (B) Immunoblot (IB) analysis addressing vitronectin protein expression in ARPE-19, hiPSC-RPE, Y79, WERI-Rb1, HUVEC, and HEK293-EBNA cells. HEK293-EBNA cells transfected with expression vectors for VTN<sub>rs704:C</sub> served as positive control; no cells were added to the negative control. Cell lysates were subjected to IB analyses using antibodies against vitronectin and ACTB (loading control). (Figure modified from Biasella et al., 2020<sup>246</sup>).

### 4.2 Influence of Genetic Variant rs704 on Vitronectin Expression

#### 4.2.1 Comparison of mRNA Expression for VTN Variants

An effect of rs704 on VTN transcription was studied in hiPSC-RPE cells and neural retinal samples from different donors which were heterozygous for rs704 (**Figure 9A**). After RNA isolation and cDNA synthesis, a semi-quantitative sequencing approach was performed to study differences in the mRNA expression of VTN<sub>rs704:C</sub> and VTN<sub>rs704:T</sub> alleles. Prior to the analysis, the sensitivity of the method was determined. Specifically, a dilution series was performed with a mixture of different concentrations of recombinant VTN cDNA variants (pcDNA3.1\_VTN<sub>rs704:C</sub> and pcDNA3.1\_VTN<sub>rs704:T</sub>). Differences in VTN<sub>rs704:C</sub> and VTN<sub>rs704:T</sub> concentrations are reflected in the sequence chromatogram by differences in peak height (**Figure 9B**). Electropherogram peaks were similar for heterozygous DNA samples of hiPSC-RPE cells and neural retinal tissues at the T and C allele position (**Figure**

**9A, C).** This suggests similar levels of *VTN*\_rs704:C and *VTN*\_rs704:T transcripts in the heterozygous samples and thus no significant effect of rs704 on vitronectin mRNA expression.

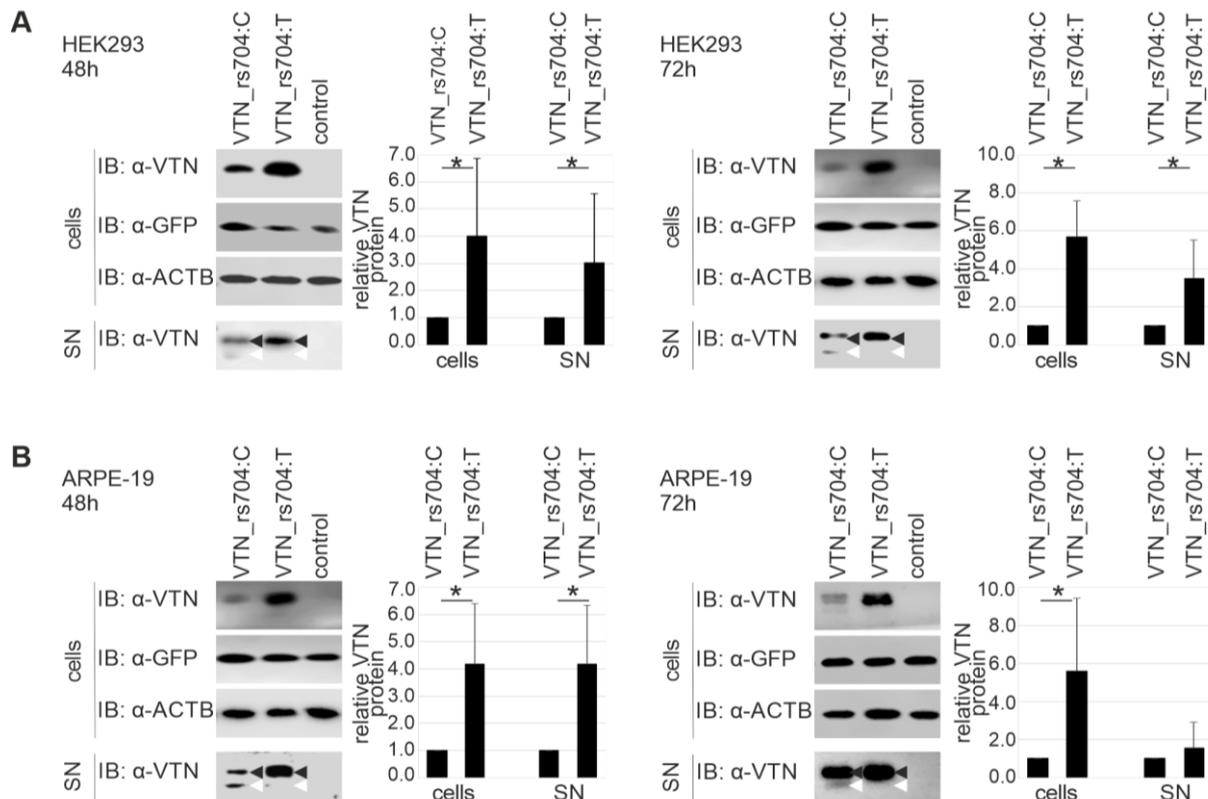

**Figure 9: Effect of rs704 on *VTN* mRNA expression.**

(A) DNA sequence chromatograms obtained from amplification of the *VTN* region harbouring rs704 from genomic DNA (gDNA) of hiPSC-RPE cells and human neural retinal samples (hNeurRet). (B) Titration series with recombinant *VTN* cDNA variants derived from the non-risk (rs704:C) or the risk (rs704:T) haplotype (ratio of C:T allele given in the figure). (C) Expression analysis of endogenous *VTN* cDNA variants *VTN*\_rs704:C and *VTN*\_rs704:T in hiPSC-RPE cells or human retinal tissues (hNeurRet) of different donors by semi-quantitative sequencing. (Figure modified from Biasella et al., 2020<sup>246</sup>).

#### 4.2.2 Comparison of Protein Expression and Processing for Vitronectin Isoforms

The impact of rs704 on vitronectin protein expression was analysed *via* heterologous expression of VTN\_rs704:C and VTN\_rs704:T. To that end, HEK293-EBNA and ARPE-19 cells were transfected with expression constructs for VTN\_rs704:C and VTN\_rs704:T, or with an empty control expression vector. As a control, co-transfection with the expression vector for GFP monitored comparable transfection efficiency for the different conditions tested. After 48 and 72 h, culture medium and cell lysates were collected and expression of the two heterologously expressed vitronectin isoforms was compared by western blot analysis. After densitometric quantification a significant increase in the amount of cellular VTN\_rs704:T compared to VTN\_rs704:C (48 h,  $3.99 \pm 2.88$ -fold increase; 72 h,  $5.66 \pm 1.91$ -fold increase;  $p < 0.05$  for both time points) was observed. An increase in the amount of VTN\_rs704:T compared to VTN\_rs704:C was also observed in the culture medium of the cells (48 h,  $3.03 \pm 2.52$ -fold increase; 72 h,  $3.47 \pm 2.05$ -fold increase;  $p < 0.05$  for both time points; **Figure 10A**). Similarly, densitometric quantification also revealed a statistically significant increase in the amount of VTN\_rs704:T compared to VTN\_rs704:C in transfected ARPE-19 cells (48 h,  $4.19 \pm 2.20$ -increase; 72 h,  $5.60 \pm 3.83$ -increase;  $p < 0.05$  for both time points), as well as increased secretion of VTN\_rs704:T compared to VTN\_rs704:C into the cultivation medium (48 h,  $4.17 \pm 2.16$ -increase,  $p < 0.05$ ; 72 h,  $1.55 \pm 1.36$ -increase,  $p > 0.05$ ) (**Figure 10B**). VTN\_rs704:T secreted from both cell types appeared mainly as a single-chain form of 75 kDa (indicated by the black arrowhead in **Figure 10A, B**). In contrast, secreted VTN\_rs704:C appeared as a mixture of the cleaved form (65 kDa, white arrowhead in **Figure 10A, B**) and the uncleaved single-chain form (75 kDa, black arrowhead in **Figure 10A, B**).

**Figure 10: Effect of rs704 on vitronectin protein expression and processing.**

(A) HEK293-EBNA and (B) ARPE-19 cells were transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T, or with an empty expression vector (control). Co-transfection with a GFP expression vector was performed as a transfection control. Forty-eight and 72 h after transfection, cell lysate and culture medium (supernatant, SN) of transfected cells were subjected to immunoblot (IB) analysis with antibodies against vitronectin ( $\alpha$ -VTN) and GFP ( $\alpha$ -GFP). The ACTB immunoblot served as loading control. The black and white arrowheads represent vitronectin in its full-chain (uncleaved) and cleaved form, respectively. After densitometric quantification, vitronectin signals were normalized against GFP. Data represent the mean  $\pm$  SD of four biological replicates, calibrated against VTN\_rs704:C. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Mann-Whitney U test). (Figure modified from Biasella et al., 2020<sup>246</sup>).

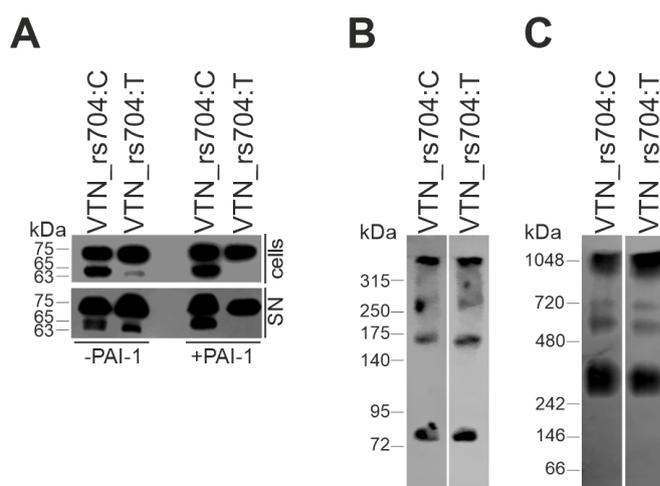

### 4.3 Effect of rs704 on the Endogenous Proteolytic Cleavage of Vitronectin

*In vivo*, vitronectin is mainly processed by two proteases cleaving at two closely adjacent cleavage sites, and thus both resulting in cleavage products of similar molecular weight (63 and 65 kDa, as well as 12 and 10 kDa). The furin protease cleaves at the carboxyl-terminal side of R398 and was already reported to be affected by the rs704-associated amino acid exchange in aa 400<sup>204,237</sup>. The plasmin protease cleaves at the carboxyl-terminal side of R380<sup>257</sup>. To assess the effect of furin and plasmin proteases on heterologously expressed VTN\_rs704:C and VTN\_rs704:T in HEK293-EBNA (Figure 7; Figure 10), the processing of heterologously expressed vitronectin was compared with and without inhibition of the plasmin protease. To inhibit plasmin cleavage, HEK293-EBNA cells were co-transfected with expression vectors for PAI-1, a known inhibitor of plasmin formation<sup>257</sup>. In western blot analyses of cell lysates and culture media from cells heterologously expressing VTN\_rs704:C and VTN\_rs704:T but not PAI-1, both vitronectin isoforms appeared as a mixture of the uncleaved, 75 kDa, species and the cleaved species (differentiation between

the 65 and 63 kDa vitronectin species not feasible in western blot) (**Figure 11A**). Again, VTN\_rs704:T showed less susceptibility to endoproteolytic cleavage than VTN\_rs704:C. In the presence of heterologously co-expressed PAI-1, no cleaved species were detected for VTN\_rs704:T, whereas VTN\_rs704:C was cleaved as usual. This suggests that the rs704-induced exchange of aa from T400 to M400 interferes with furin cleavage and that the clipped product relative to the VTN\_rs704:T isoform observed in experiments in which plasmin was not inhibited (without co-transfection of PAI-1) results rather from plasmin cleavage on the carboxy-terminal side of R380 thus representing a 63 kDa isoform (**Figure 11A**).

#### 4.4 Effect of rs704 on Vitronectin Multimerization

Purified isoforms VTN\_rs704:C and VTN\_rs704:T were subjected to non-reducing SDS-PAGE (**Figure 11B**) and Blue Native PAGE (**Figure 11C**) to follow vitronectin self-aggregation into higher-order multimers (reported up to 16-mer)<sup>205</sup>, stabilized by disulphide bonds or non-covalent interactions, respectively. Non-reducing SDS-PAGE revealed species of approximately 75 kDa for both vitronectin isoforms corresponding to the respective monomeric forms, as well as higher molecular weights species from 150 kDa up to > 300 kDa, representing disulphide bond-stabilized vitronectin multimers (**Figure 11B**, representative of three independent experiments). Blue Native PAGE showed high molecular weight species in the range of 300-1050 kDa (**Figure 11C**, representative of three independent experiments). In both approaches, VTN\_rs704:C and VTN\_rs704:T showed comparable multimerization patterns and thus no effect of rs704 on vitronectin self-aggregation.

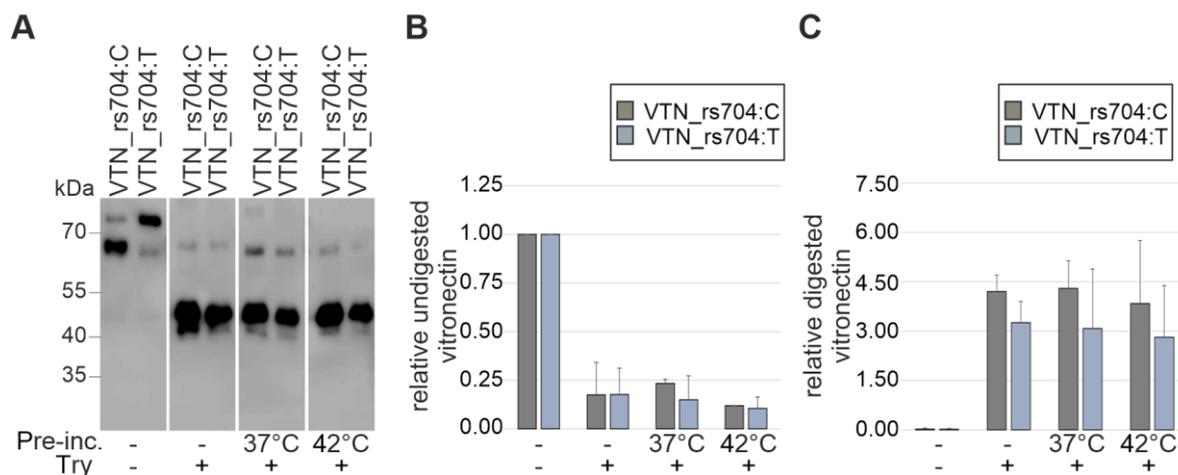

**Figure 11: Effect of rs704 on proteolytic cleavage and multimerization of vitronectin.**

(A) HEK293-EBNA cells were transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T in combination with an empty (control) expression vector (-PAI-1) or with a PAI-1 expression vector (+PAI-1). After 48 h, transfected cells, and their culture medium (supernatant, SN) were subjected to western blot analysis with antibodies against vitronectin. (B) Non-reducing SDS-PAGE and (C) BN-PAGE with recombinant vitronectin isoforms, followed by western blot analysis with antibodies against vitronectin. (Figures B and C were modified from Biasella et al., 2020<sup>246</sup>).

#### 4.5 Effect of rs704 on Vitronectin Stability

Differences between VTN\_rs704:C and VTN\_rs704:T in thermodynamic stability were assessed by the partial proteolysis assay, which monitors susceptibility of proteins to trypsin-mediated digestion after partial thermal denaturation. For thermal protein denaturation, the two purified vitronectin isoforms VTN\_rs704:C and VTN\_rs704:T were pre-incubated for 10 min at 37°C or 42°C. Proteolysis was performed by subsequent incubation with TPCK-trypsin for 5 min. Digestion was followed by western blot analysis with antibodies against vitronectin. Untreated purified vitronectin isoforms exhibited the characteristic migration pattern described in section 4.2.2 and 4.3, with a major molecular weight species of approximately 65 kDa for VTN\_rs704:C (predominantly present in the cleaved form) and a 75 kDa for VTN\_rs704:T (predominantly present in the uncleaved form) (**Figure 12A**). Incubation with TPCK-trypsin resulted in rapid digestion of both vitronectin isoforms, visible by the strong decrease of the 75 and 65 kDa species and an increase in cleavage products with molecular weights between 40 and 55 kDa (**Figure 12A**). Similar results were obtained when the proteins were first denatured at 37 or 42°C for 10 min and then incubated with TPCK-trypsin, hence the partial thermal denaturation did not seem to strongly influence the accessibility of both vitronectin isoforms to trypsin (**Figure 12**). This was also evident after densitometric quantification of three independent experiments (**Figure 12B, C**): The levels of undigested vitronectin species was reduced to about one fifth by trypsin treatment (**Figure 12B**), while the levels of digestion products with a molecular weight between 40 and 55 kDa, appearing only in trypsin-treated samples, was not affected by thermal pre-treatment (**Figure 12C**). Notably, the amount of 40-55 kDa digestion products from VTN\_rs704:C appeared slightly higher than that of VTN\_rs704:T in all three trypsin-mediated digestion assays (**Figure 12C**), however, this trend was not statistically significant.

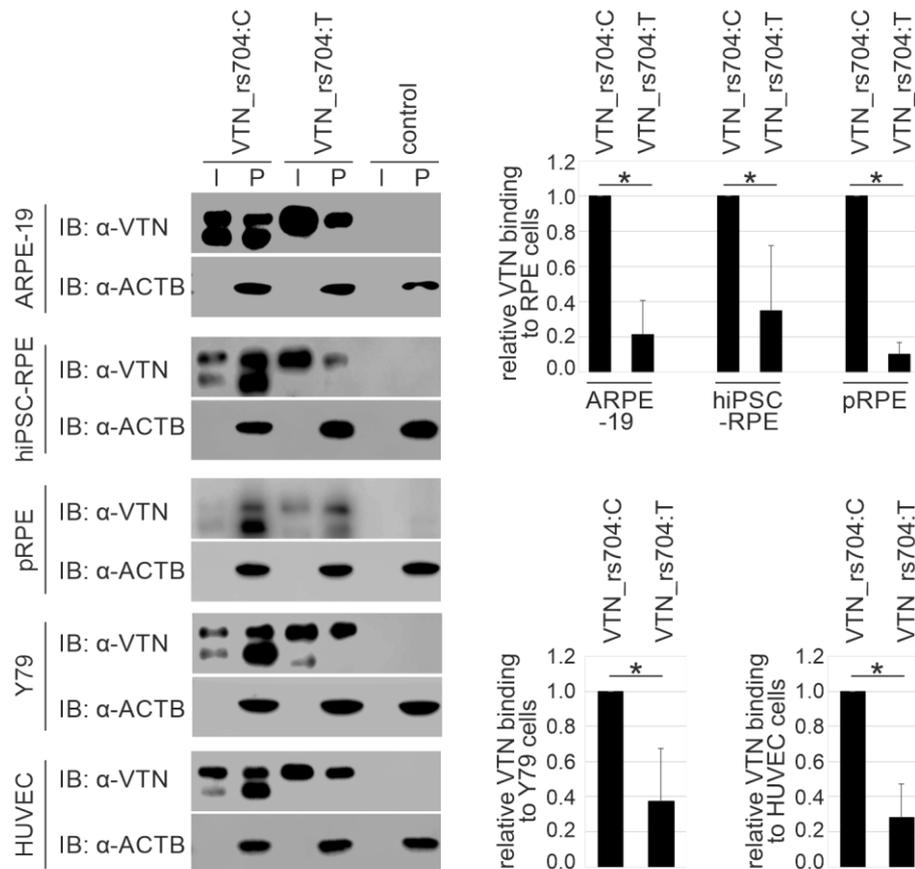

**Figure 12: Effect of rs704 on vitronectin stability.**

Purified recombinant VTN\_rs704:C and VTN\_rs704:T, untreated or previously pre-incubated at 37 and 42°C, were subjected to proteolysis with TPCK-trypsin (Try) at 37°C for 5 min. (A) Samples were subjected to immunoblot analysis with antibody against vitronectin. After densitometry, the signals from (B) relative levels of undigested vitronectin and (C) relative levels of digestions products (of size between 40 and 55 kDa) from vitronectin isoforms were calibrated against signals from the respective untreated vitronectin isoform (undigested, full-length). Data represent the mean  $\pm$  SD of three biological replicates.

#### 4.6 Effect of rs704 on the Capacity of Vitronectin to Bind Retinal and Endothelial Cell Lines

The two vitronectin isoforms VTN\_rs704:C and VTN\_rs704:T were compared in their ability to bind the retinal cell lines ARPE-19, hiPSC-RPE, porcine RPE, Y79 and the endothelial cell line HUVEC. Cells were incubated in medium containing the heterologously expressed vitronectin isoforms VTN\_rs704:C and VTN\_rs704:T, or in vitronectin-free control medium for 1 h at 37°C. After repeated washing steps, cells were lysed and subjected to western blot analysis with antibodies against vitronectin and ACTB (loading control). It was observed that VTN\_rs704:C and VTN\_rs704:T both bound to all cell lines tested. However, compared to VTN\_rs704:C, VTN\_rs704:T showed a statistically significantly decreased binding to all cell lines (densitometric quantification of four to six independent experiments revealed a reduction of VTN\_rs704:T binding to 21.3%  $\pm$  19.4% in ARPE-19, to 34.8%  $\pm$  37.0% in hiPSC-RPE, to 10.2%  $\pm$  6.7% in porcine RPE, to 27.9%  $\pm$  19.2% in HUVEC, and to 37.1%  $\pm$  30.3% for Y79 cells, compared to VTN\_rs704:C ( $p < 0.05$  for all cell lines; **Figure 13**).

**Figure 13: Effect of rs704 on vitronectin binding to retinal and endothelial cells.**

ARPE-19, hiPSC-RPE, porcine RPE, Y79 and HUVECs were incubated with vitronectin-containing input (I, culture medium of HEK293-EBNA cells transfected with expression vectors for VTN\_rs704:C and VTN\_rs704:T, adjusted for vitronectin concentrations) or control input. After washing, cell pellets (P) were subjected to western blot analysis with antibodies against vitronectin ( $\alpha$ -VTN) and ACTB ( $\alpha$ -ACTB), as loading control. After densitometric quantification, vitronectin signals were normalized against ACTB and vitronectin in the input. Data represent the mean  $\pm$  SD of four (hiPSC-RPE and pRPE), five (ARPE-19 and HUVECs), or six (Y79) biological replicates, calibrated against VTN\_rs704:C. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Mann-Whitney U test). (Figure modified from Biasella et al., 2020<sup>246</sup>).

#### 4.7 Role of VTN\_rs704:C and VTN\_rs704:T in AMD-associated RPE Cellular Processes

The following analyses aimed to compare the effect of the two vitronectin isoforms VTN\_rs704:C and VTN\_rs704:T on AMD-associated cellular processes, specifically cell adhesion, autophagy, viability, and activation of ERK signalling<sup>209,234,271,272</sup> in cultured RPE cells.

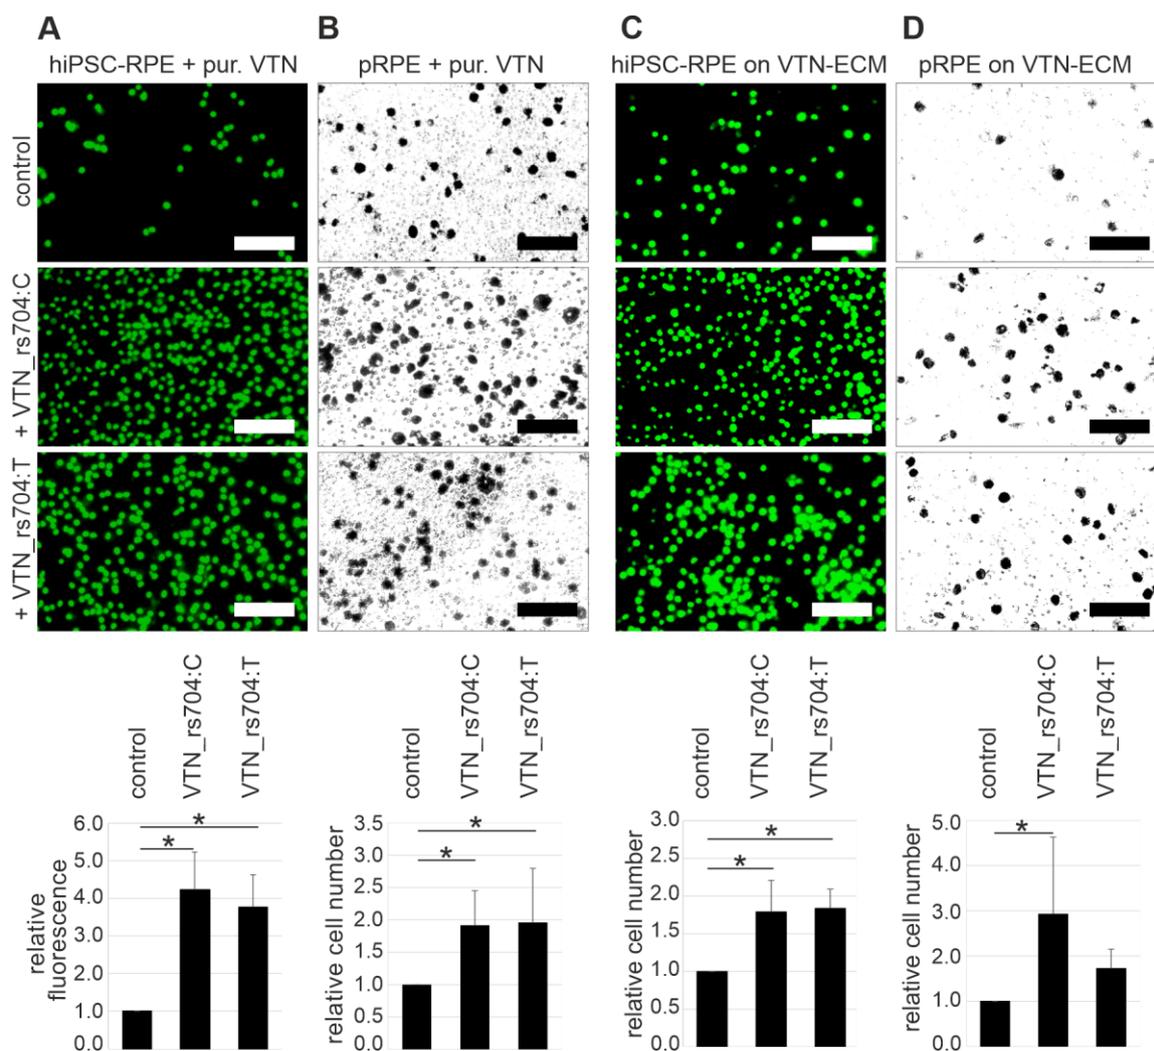

##### 4.7.1 Influence of VTN\_rs704:C and VTN\_rs704:T on RPE Cell Adhesion

The role of VTN\_rs704:C and VTN\_rs704:T on RPE cell adhesion was assessed in hiPSC-RPE and porcine RPE cells.

First, adhesion of resuspended cells on the cell culture well in the presence of purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate was compared. hiPSC-RPE cells were incubated for 24 h with recombinant vitronectin isoforms or control eluate, followed by

fluorescent labelling and intensive washing. Next, the fluorescence emitted by cells attached to the culture well was measured (**Figure 14A**). A quantification of seven independent experiments revealed an increase in the fluorescence signal to  $4.24 \pm 0.99$  after treatment with VTN\_rs704:C and to  $3.78 \pm 0.86$  after treatment with VTN\_rs704:T compared to control ( $p < 0.05$  between vitronectin-treated samples and control, **Figure 14A**). The adhesion of porcine RPE cells was assessed after 18 h of treatment with recombinant vitronectin isoforms or control eluate. Due to the strong pigmentation of primary porcine RPE cells, fluorescence labelling of these cells was not feasible. Instead, cell adhesion was assessed by taking microscopic images and counting cells adhered to the culture plate after intensive washing steps. Again, the presence of the two recombinant vitronectin isoforms increased cell adhesion of porcine RPE cells compared to control treatment (a quantification of four independent replicates revealed an increase in the relative number of adherent cells to  $1.92 \pm 0.53$  with VTN\_rs704:C and to  $1.96 \pm 0.83$  with VTN\_rs704:T compared to control treatment;  $p < 0.05$  between vitronectin-treated and control samples, **Figure 14B**).

The adhesion of hiPSC-RPE and porcine RPE cells was also assessed onto ECM containing recombinant VTN\_rs704:C or VTN\_rs704:T, as well as onto vitronectin-free control ECM (produced from ARPE-19 cells transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T or with an empty expression vector, respectively). Cell suspensions were added onto ECM-containing filters for 40 min at 37°C, followed by several washing steps. Adherent hiPSC-RPE cells (again fluorescently labelled) and porcine RPE cells were counted from microscopic photographs. Quantification of four or five independent experiments, respectively, showed that the presence of both vitronectin isoforms in the matrices facilitated cell adhesion in hiPSC-RPE cells ( $1.79 \pm 0.41$  with VTN\_rs704:C and  $1.84 \pm 0.25$  with VTN\_rs704:T compared to control;  $p < 0.05$  between control ECM and ECM containing vitronectin, **Figure 14C**) as well as in porcine RPE cells ( $2.92 \pm 1.71$  with VTN\_rs704:C and  $1.73 \pm 0.42$  with VTN\_rs704:T compared to control;  $p < 0.05$  between VTN\_rs704:C-containing ECM and control, **Figure 14D**). However, the analyses showed no differences in the effect of VTN\_rs704:C and VTN\_rs704:T.

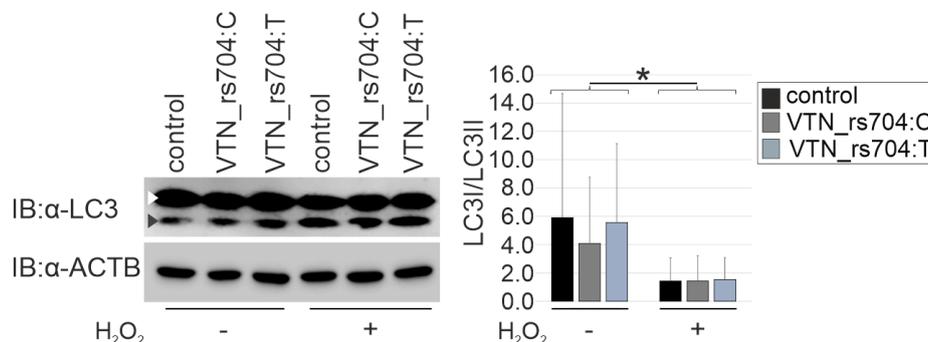

**Figure 14: Effect of VTN\_rs704:C and VTN\_rs704:T on RPE cell adhesion.**

(A) hiPSC-RPE and (B) freshly isolated porcine RPE (pRPE) cell suspension were incubated for 24 h and 18 h, respectively, in the presence of purified recombinant VTN\_rs704:C, VTN\_rs704:T, or control eluate. Subsequently, cell adhesion was determined measuring fluorescence of fluorescently labelled cells in a spectrophotometer (A) or counting cells from 4× micrographs (B) using ImageJ. (C) hiPSC-RPE cells and (D) freshly isolated pRPE were incubated for 40 min on VTN\_rs704:C- or VTN\_rs704:T-containing ECM or on control ECM. Subsequently, adherent cells were determined by counting cells from 4× micrographs with ImageJ. Data represent mean ± SD of seven (A), four (B, D), or five (C) independent replicates, calibrated against the control. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test and Bonferroni correction). Micrographs shown in the figure were taken at 10× magnification (standard, 200 μm). (Figure modified from Biasella et al., 2020<sup>246</sup>).

#### 4.7.2 Influence of VTN\_rs704:C and VTN\_rs704:T on RPE Cell Autophagy

An effect of VTN\_rs704:C and VTN\_rs704:T on cell autophagy was examined in ARPE-19 cells. To induce cell autophagy, cells were treated with purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate, with or without exposure to 1 mM H<sub>2</sub>O<sub>2</sub> for 2 h. After 2 h, cells were lysed, and subjected to western blot analysis against autophagy marker LC3, following the ratio of its isoforms LC3-I (decreasing with autophagy induction) and LC3-II (increasing with autophagy induction)<sup>266</sup>. Densitometric quantification of four independent experiments revealed a significant decrease in the LC3-I/LC3-II ratio in cells subjected to H<sub>2</sub>O<sub>2</sub> compared to cells without H<sub>2</sub>O<sub>2</sub> treatment ( $p < 0.05$  between H<sub>2</sub>O<sub>2</sub>-treated samples compared to

untreated samples), demonstrating successful induction of autophagy in H<sub>2</sub>O<sub>2</sub> treated cells (**Figure 15**). However, the two vitronectin isoform revealed a similar LC3-I/LC3-II ratio, in H<sub>2</sub>O<sub>2</sub>-treated samples as well as in controls (H<sub>2</sub>O<sub>2</sub>-free) (**Figure 15**).

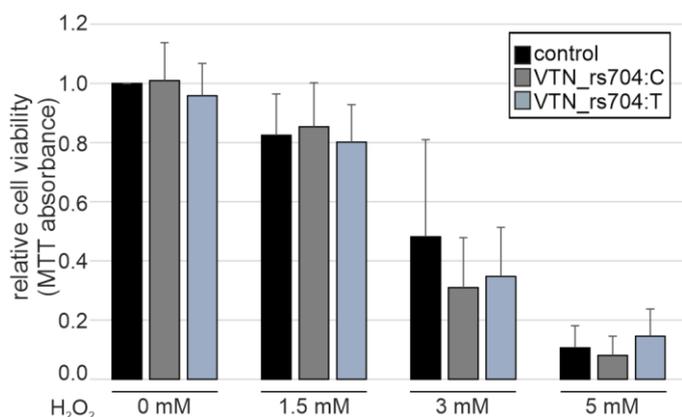

**Figure 15: Effect of VTN\_rs704:C and VTN\_rs704:T on RPE autophagy.**

ARPE-19 cells were pre-incubated for 1 h with purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate. Subsequently, cells were exposed for 2 h to 1mM H<sub>2</sub>O<sub>2</sub> (+H<sub>2</sub>O<sub>2</sub>) or treated under the same conditions but without H<sub>2</sub>O<sub>2</sub> (-H<sub>2</sub>O<sub>2</sub>), in the presence of fresh purified recombinant proteins. Cells were subjected to western blot analysis with antibodies against LC3 (α-LC3) and ACTB (α-ACTB) as loading control. After densitometric quantification, LC3I signals (white arrowhead) were normalised against the respective LC3II signals (black arrowhead). Data represent the mean ± SD of four biological replicates. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Mann-Whitney U test).

#### 4.7.3 Influence of VTN\_rs704:C and VTN\_rs704:T on RPE Cell Viability

Cell death of RPE cells particularly in response to oxidative stress is a characteristic pathological sign in AMD<sup>234,273,274</sup>. A putative role for VTN\_rs704:C and VTN\_rs704:T in RPE cell viability was assessed in ARPE-19 cells subjected to different levels of oxidative stress. To induce oxidative stress, ARPE-19 were exposed to 0, 1.5, 3, and 5 mM of H<sub>2</sub>O<sub>2</sub> for 2 h at 37°C, in the presence of purified VTN\_rs704:C, VTN\_rs704:T or control eluate. After a period of 18 h allowing the cells to recover in the presence of VTN\_rs704:C, VTN\_rs704:T or control eluate, cells were subjected to the MTT assay, measuring the activity of NAD(P)H-dependent oxidoreductase enzymes as a marker for cell viability. Quantification of six independent experiments showed a reduction in oxidoreductase activity and thus viability of ARPE-19 cells with increasing concentrations of H<sub>2</sub>O<sub>2</sub> (**Figure 16**). No effect of VTN\_rs704:C and VTN\_rs704:T in comparison to control eluate treatment was observed for all oxidative stress conditions tested (**Figure 16**).

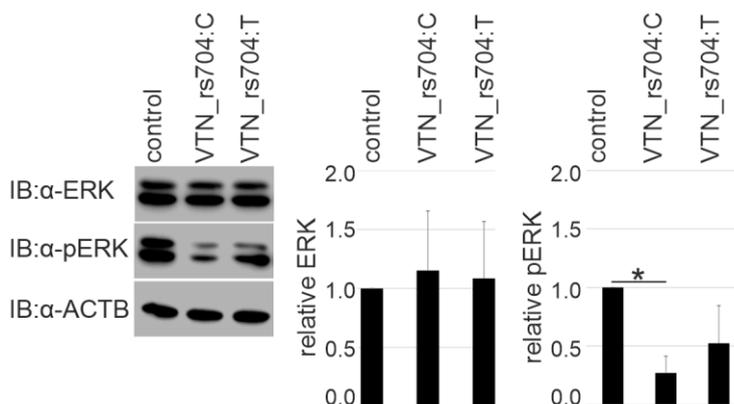

**Figure 16: Effect of VTN\_rs704:C and VTN\_rs704:T on RPE cell viability.**

ARPE-19 cells were exposed for 2 h to 0, 1.5, 3 and 5 mM H<sub>2</sub>O<sub>2</sub> in the presence of purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate. After a period of 18 h allowing the cells to recover in the presence of purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate, cells were subjected to the MTT assay. Data represent the mean  $\pm$  SD of six biological replicates calibrated against control at 0 mM H<sub>2</sub>O<sub>2</sub>.

#### 4.7.4 Influence of VTN\_rs704:C and VTN\_rs704:T on ERK Signalling in RPE cells

To analyse effects of VTN\_rs704:C and VTN\_rs704:T on ERK signalling in RPE cells, ARPE-19 cells were incubated with VTN\_rs704:C, VTN\_rs704:T or control eluate for 2 h at 37 °C. Subsequently, cells were harvested, and subjected to western blot analysis following phosphorylation and thus activation of the ERK signalling marker ERK1/2<sup>275,276</sup>. Compared to control, cells treated with the two vitronectin isoforms depicted a down-regulation of phosphorylated ERK1/2 (**Figure 17**), specifically, densitometric quantification of three independent experiments revealed a reduction to 27.0%  $\pm$  14.3% with VTN\_rs704:C and to 52.3%  $\pm$  32.1% with VTN\_rs704:T, compared to control eluate;  $p < 0.05$  between VTN\_rs704:C-treated cells and control; **Figure 17**).

**Figure 17: Effect of VTN\_rs704:C and VTN\_rs704:T on ERK1/2 activation in RPE cells.**

ARPE-19 cells were treated with purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate. After 2h, cells were subjected to western blot analysis with antibodies against ERK1/2 ( $\alpha$ -ERK), phosphorylated ERK1/2 ( $\alpha$ -pERK) and ACTB ( $\alpha$ -ACTB), as loading control. After densitometric quantification, ERK1/2 and phosphorylated ERK1/2 (pERK) signals were normalised against ACTB. Data represent the mean  $\pm$  SD of three biological replicates calibrated against the control. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test and Bonferroni correction).

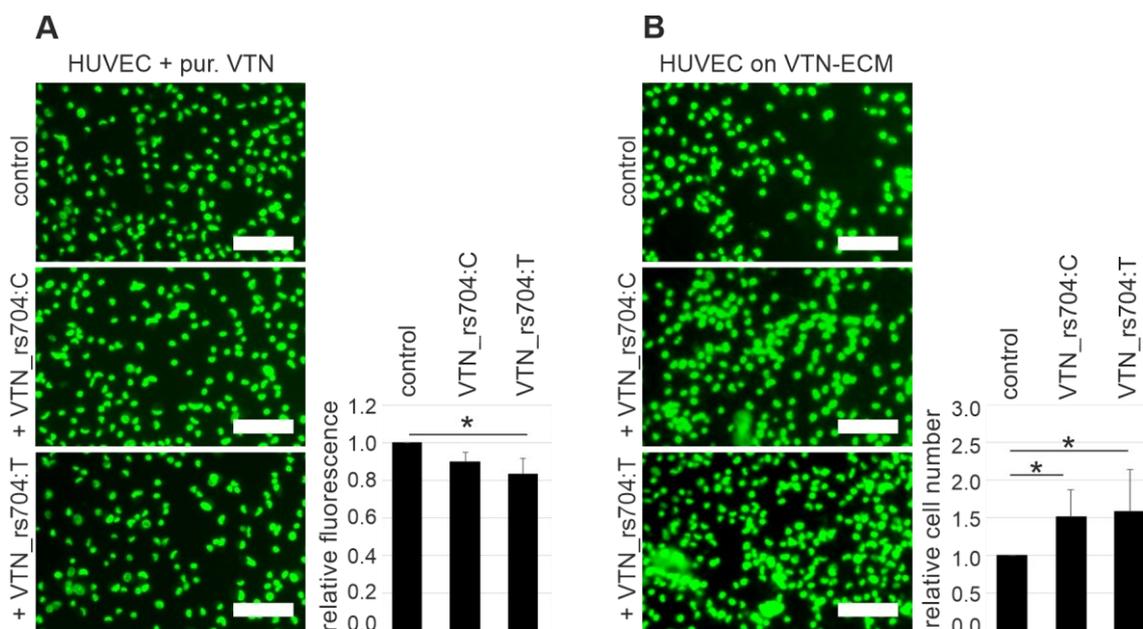

#### 4.8 Influence of VTN\_rs704:C and VTN\_rs704:T in AMD-associated Endothelial Cellular Processes

Aberrant angiogenesis is a hallmark of NV, one of the two late-stage forms of AMD<sup>211</sup>. The following analyses aimed to investigate an effect of VTN\_rs704:C and VTN\_rs704:T on cellular processes closely related to angiogenesis, i.e. endothelial cell adhesion, autophagy, viability, ERK-signalling, migration and tubulogenesis<sup>277-279</sup>.

##### 4.8.1 Influence of VTN\_rs704:C and VTN\_rs704:T on Endothelial Cell Adhesion

The effect of VTN\_rs704:C and VTN\_rs704:T on endothelial cell adhesion was studied in HUVEC cells following their adherence to the culture flask after incubation with purified recombinant VTN\_rs704:C, VTN\_rs704:T, or control eluate for 20 min at 37 °C. After incubation, cells were fluorescently labelled, and repeatedly washed to remove non-adherent cells. Subsequently, the fluorescence emitted by cells attached to the culture vessel was measured photometrically (**Figure 18A**). A quantification of five independent experiments revealed that both vitronectin isoforms slightly decreased fluorescence (and thus cellular adhesion) to  $0.90 \pm 0.05$  for VTN\_rs704: C and  $0.83 \pm 0.09$  for VTN\_rs704: T ( $p < 0.05$  between VTN\_rs704: T and control, **Figure 18A**) with no statistical difference between the two isoforms.

In an alternative approach, HUVECs were seeded onto vitronectin-containing or vitronectin-free ECM produced by ARPE-19 cells (see 3.31.2) and incubated for 5 min at 37 °C. Cells were then fluorescently labelled and repeatedly washed. After taking microscopic photographs, cells adhering to the ECM were counted. Quantification of five independent experiments revealed that the number of adherent cells increased with the presence of vitronectin in the matrices (increase to  $1.52 \pm 0.36$  with VTN\_rs704:C and to  $1.59 \pm 0.56$  with VTN\_rs704:T compared to control;  $p < 0.05$  between control and VTN\_rs704:C- or VTN\_rs704:T-containing ECM, **Figure 18B**), again with no statistical difference between the two isoforms.

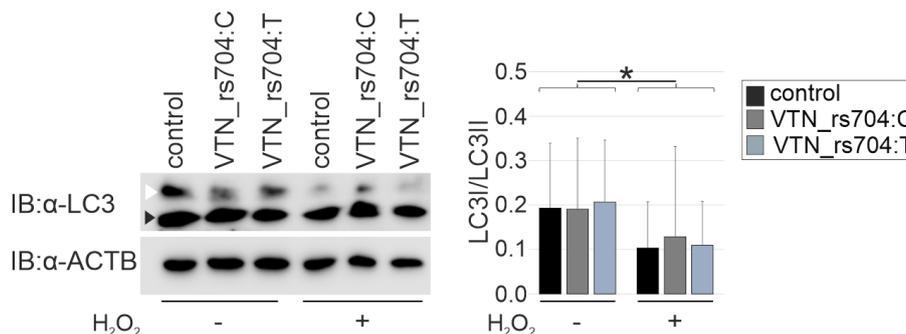

**Figure 18: Effect of VTN\_rs704:C and VTN\_rs704:T on endothelial cell adhesion.**

(A) HUVECs were incubated for 20 min with purified recombinant VTN\_rs704:C, VTN\_rs704:T, or control eluate. Subsequently, cell adhesion was determined measuring fluorescence of fluorescently labelled cells in a spectrophotometer. (B) HUVECs were incubated for 5 min on VTN\_rs704:C- or VTN\_rs704:T-containing ECM, or on control ECM. Subsequently, adherent cells were determined by counting cells from 4× micrographs with ImageJ. Data represent mean ± SD of five (A, B) independent replicates, calibrated against the control. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal–Wallis test, followed by Dunn's multiple comparison test and Bonferroni correction). Micrographs shown in the figure were taken at 10× magnification (standard, 200 μm). (Figure modified from Biasella et al., 2020<sup>246</sup>).

#### 4.8.2 Influence of VTN\_rs704:C and VTN\_rs704:T on Endothelial Cell Autophagy

An effect of VTN\_rs704:C and VTN\_rs704:T on cell autophagy was examined in HUVEC cells subjected to oxidative stress (*via* H<sub>2</sub>O<sub>2</sub> treatment) inducing autophagy<sup>280</sup>. Cells were treated for 24 h at 37°C with VTN\_rs704:C, VTN\_rs704:T or control eluate, and with 0 mM H<sub>2</sub>O<sub>2</sub> or 1 mM H<sub>2</sub>O<sub>2</sub>. After 24 h, cells were harvested, and western blot analysis was conducted with cell lysates by using antibodies against autophagy marker LC3, comparing the ratio of its isoforms LC3-I (decreasing with autophagy induction) and LC3-II (increasing with autophagy induction)<sup>266</sup>. Densitometric quantification of six independent experiments revealed a decrease in the LC3-I/LC3-II ratio in HUVECs subjected to H<sub>2</sub>O<sub>2</sub> compared to HUVECs incubated without H<sub>2</sub>O<sub>2</sub> ( $p < 0.05$  between H<sub>2</sub>O<sub>2</sub>-treated samples compared to H<sub>2</sub>O<sub>2</sub>-free samples; **Figure 19**), demonstrating the induction of autophagy in the oxidatively stressed cells. However, no statistical difference between VTN\_rs704:C and VTN\_rs704:T was observed (**Figure 19**).

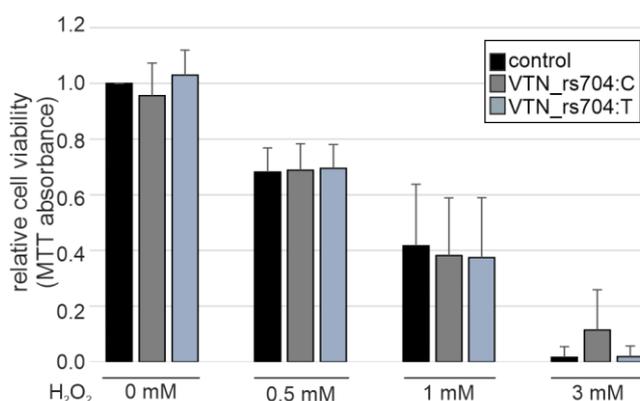

**Figure 19: Effect of VTN\_rs704:C and VTN\_rs704:T on endothelial cell autophagy.**

HUVECs were pre-incubated for 1 h with purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate. Subsequently, cells were exposed for 24 h to 1mM H<sub>2</sub>O<sub>2</sub> (+H<sub>2</sub>O<sub>2</sub>) or treated under the same conditions but without H<sub>2</sub>O<sub>2</sub> (-H<sub>2</sub>O<sub>2</sub>), in the presence of fresh purified recombinant proteins. Cells were subjected to western blot analysis with antibodies against LC3 (α-LC3) and ACTB (α-ACTB) as loading control. After densitometric quantification, LC3I signals (white arrowhead) were normalised against the respective LC3II signals (black arrowhead). Data represent the mean ± SD of six biological replicates. Asterisks indicate statistically significant differences (\*p < 0.05, Mann-Whitney U test).

#### 4.8.3 Influence of VTN\_rs704:C and VTN\_rs704:T on Endothelial Cell Viability

The effect of VTN\_rs704:C and VTN\_rs704:T on endothelial cell viability was studied in HUVECs exposed to different levels of oxidative stress. To induce oxidative stress, HUVECs were exposed to 0, 0.5, 1 and 3 mM of H<sub>2</sub>O<sub>2</sub> for 2 h at 37°C in the presence of VTN\_rs704:C, VTN\_rs704:T or control eluate. After a period of 18 h, allowing the cells to recover in the presence of VTN\_rs704:C, VTN\_rs704:T or control eluate, cells were subjected to the MTT assay. Quantification of six independent experiments showed a reduction in oxidoreductase activity and thus cell viability with increasing concentrations of H<sub>2</sub>O<sub>2</sub> (Figure 20). No difference was observed between cells treated with VTN\_rs704:C, VTN\_rs704:T, or control eluate, under all oxidative stress conditions applied (Figure 20).

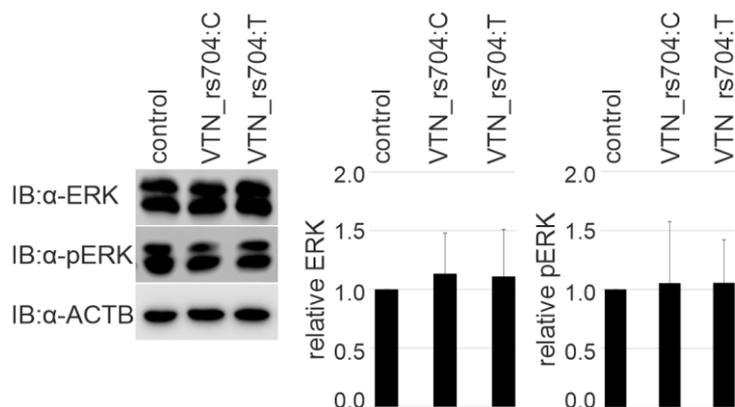

**Figure 20: Effect of VTN\_rs704:C and VTN\_rs704:T on endothelial cell viability.**

HUVEC cells were exposed to 0, 0.5, 1 and 3 mM H<sub>2</sub>O<sub>2</sub> for 2h in the presence of purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate. After a period of 18 h allowing the cells to recover in the presence of purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate, cells were subjected to the MTT assay. Data represent the mean ± SD of six biological replicates calibrated against control at 0 mM H<sub>2</sub>O<sub>2</sub>.

#### 4.8.4 Influence of VTN\_rs704:C and VTN\_rs704:T on Endothelial ERK Signalling

To investigate an effect of VTN\_rs704:C and VTN\_rs704:T on the regulation of ERK signalling in endothelial cells, HUVECs were incubated with purified recombinant VTN\_rs704:C, VTN\_rs704:T, or control eluate for 24 h at 37°C. After incubation, cells were

harvested, and subjected to western blot analysis following ERK1/2 phosphorylation as a marker of ERK signalling induction<sup>275,276</sup>. Quantification of six independent experiments revealed no differences in the cellular levels of phosphorylated ERK1/2 and thus in ERK signalling activation between vitronectin-treated cells and control-treated cells (**Figure 21**).

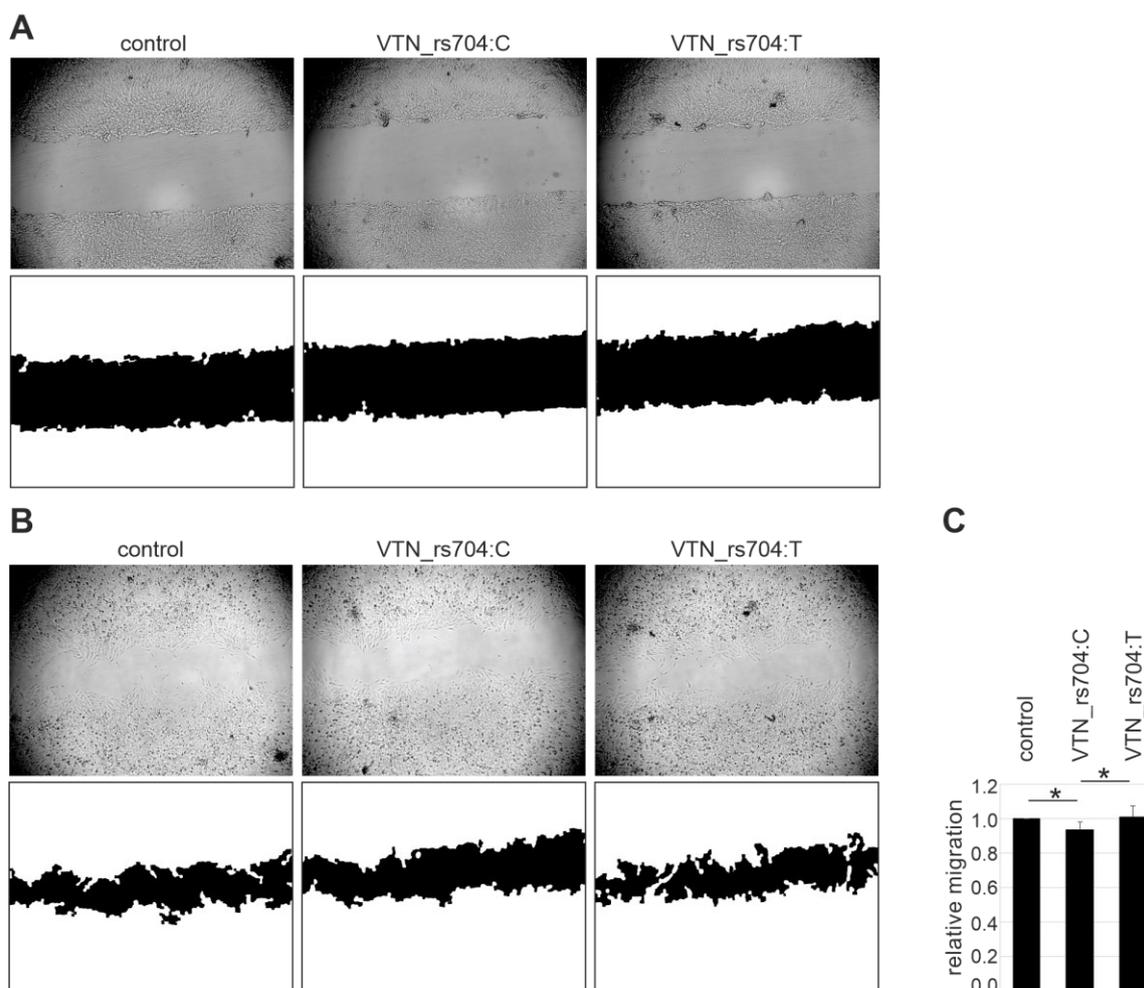

**Figure 21: Effect of VTN\_rs704:C and VTN\_rs704:T on ERK1/2 activation in endothelial cells.**

HUVEC cells were treated with purified recombinant VTN\_rs704:C, VTN\_rs704:T or control eluate. After 24 h, cells were subjected to western blot analysis with antibodies against ERK1/2 ( $\alpha$ -ERK), phosphorylated ERK1/2 ( $\alpha$ -pERK) and ACTB ( $\alpha$ -ACTB), as loading control. After densitometric quantification, ERK1/2 and phosphorylated ERK1/2 (pERK) signals were normalised against ACTB. Data represent the mean  $\pm$  SD of six biological replicates calibrated against the control.

#### 4.8.5 Influence of VTN\_rs704:C and VTN\_rs704:T on Endothelial Cell Migration

To assess an effect of VTN\_rs704:C and VTN\_rs704:T on endothelial cell migration, a “scratch-wound assay” was performed in HUVECs. To this end, HUVECs were grown overnight to confluency. Subsequently, cell monolayers were subjected to a scratch-wound (**Figure 22A**) and incubated with purified recombinant VTN\_rs704:C, VTN\_rs704:T, or control eluate for 14 h at 37°C. Wound closure and thus cell migration was monitored under the microscope. Specifically, the scratch area was measured 0 h (**Figure 22A**) and 14 h (**Figure 22B**) after the scratch was introduced. Quantification of six independent experiments showed that the presence of recombinant purified VTN\_rs704:C but not of VTN\_rs704:T slightly reduced the relative HUVEC migration (VTN\_rs704:C, 93.3%  $\pm$  5.0% compared to control;  $p < 0.05$  between VTN\_rs704:C and control, as well as between VTN\_rs704:C and VTN\_rs704:T).

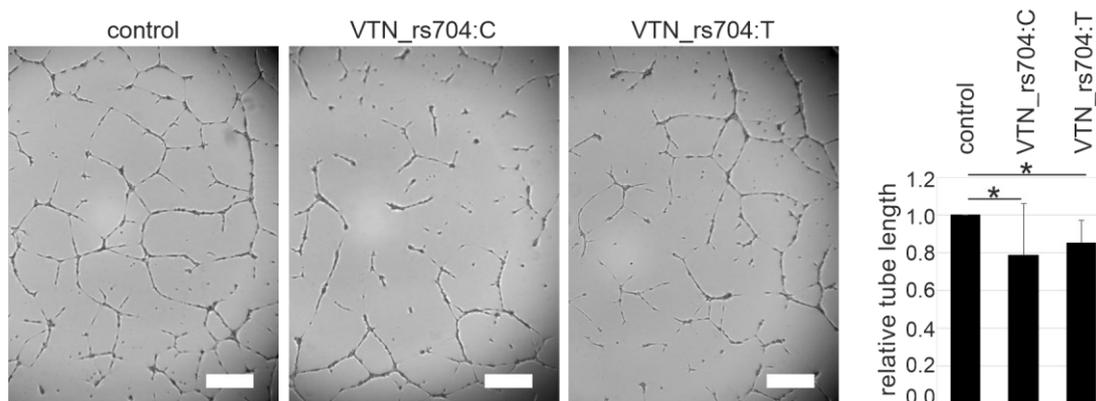

**Figure 22: Effect of VTN\_rs704:C and VTN\_rs704:T on endothelial cell migration.**

A scratch wound was introduced into HUVEC monolayers. After 14 h of incubation at 37°C in the presence of VTN\_rs704:C, VTN\_rs704:T, or control eluate, relative cell migration, defined as the percentage area closed after 14 h of incubation, was determined with ImageJ from the ratio of (B) the occupied area of the initially scratched surface to (A) the total area of the initial scratch. Data represent the mean  $\pm$  SD of six independent replicates, calibrated against the control (C). (Figure modified from Biasella et al., 2020<sup>246</sup>).

#### 4.8.6 Effect of VTN\_rs704:C and VTN\_rs704:T on Endothelial Tubulogenesis

An influence of VTN\_rs704:C and VTN\_rs704:T on the capacity of endothelial cells to form three-dimensional capillary-like tubular structures was investigated in HUVEC cells. In “tube formation assays”, HUVEC cells were seeded on Geltrex-coated plates, incubated with purified recombinant VTN\_rs704:C, VTN\_rs704:T, or control eluate, and cultured for 16 h at 37°C. The formation of capillary-like tubular structures was followed by bright-field microscopy. Both vitronectin isoforms decreased the length of tubes formed by HUVECs compared to the control (quantification of eleven independent experiments revealed a reduction to 78.8%  $\pm$  27.2% by VTN\_rs704:C and to 85.2%  $\pm$  11.9% by VTN\_rs704:T compared to control;  $p < 0.05$  between control and both vitronectin isoforms; **Figure 23**).

**Figure 23: Effect of VTN\_rs704:C and VTN\_rs704:T on endothelial tubulogenesis.**

HUVECs were cultivated in the presence of purified recombinant VTN\_rs704:C, VTN\_rs704:T, or control eluate. After 16 h, the formation of tubular-like structures was followed microscopically (standard, 400  $\mu$ m). The length of tubular-like structures was measured using ImageJ. Data represent mean  $\pm$  SD of eleven independent replicates calibrated against the control. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test and Bonferroni correction). (Figure modified from Biasella et al., 2020<sup>246</sup>).

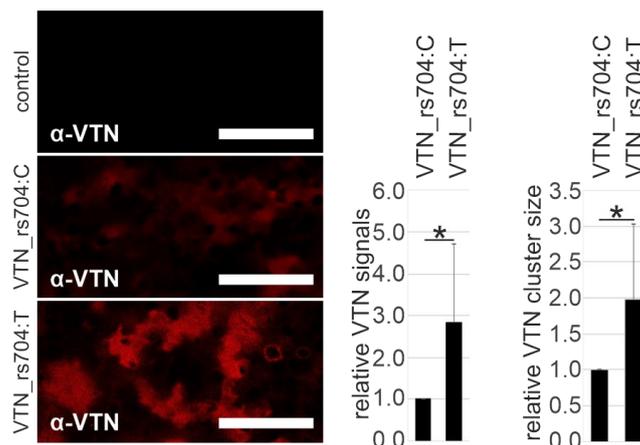

#### 4.9 Role of VTN\_rs704:C and VTN\_rs704:T on ECM Deposition and Composition

Changes in the five-layered ECM of Bruch's membrane are an early and characteristic pathological process in AMD development<sup>210</sup>. In the following analyses, an effect of VTN\_rs704:C and VTN\_rs704:T on ECM deposition by RPE cells was investigated in ARPE-19, a model system commonly used to study ECM alteration associated with AMD *in vitro*<sup>101,259,281</sup>.

ARPE-19 cells were transfected with expression vectors for VTN\_rs704:C, VTN\_rs704:T, or with a control expression vector. After 24 h, transfected cells were transferred onto Transwell filters, where ARPE-19 monolayers were cultured for 4 weeks. After that, the cells were removed from the filters and the ECM composition was analysed by immunolabelling followed by confocal microscopy.

##### 4.9.1 Influence of rs704 on Vitronectin Deposition in the ECM

First, an effect of rs704 on the deposition of vitronectin into the ECM was assessed. Immunolabeling of ARPE-19-derived ECM with antibodies against vitronectin showed an increased ECM deposition of VTN\_rs704:T compared to VTN\_rs704:C. Quantification of eight independent experiments revealed a  $2.82 \pm 1.89$ -fold increase in VTN\_rs704:T signal intensity and a  $1.99 \pm 1.04$ -fold increase in VTN\_rs704:T cluster size compared to VTN\_rs704:C ( $p < 0.05$ ). No vitronectin was detected in the control ECM derived from ARPE-19 cells transfected with the control expression vector (**Figure 24**).

**Figure 24: Effect of rs704 on vitronectin deposition into ARPE-19-deposited ECM**

ARPE-19 cells transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T or with an empty control expression vector (pcDNA3.1) were incubated for 4 weeks on Transwell filters. After 4 weeks, the inserts were decellularized and subjected to immunostaining with antibodies against vitronectin ( $\alpha$ -VTN). Confocal microscopy images were taken at 10 $\times$  magnification. Scale bars: 100  $\mu$ m. Fluorescence intensity and average cluster size were measured using ImageJ. Data represent the mean  $\pm$  SD of eight biological replicates calibrated against the control. Asterisks (\*) indicate statistically significant differences (\* $p$  < 0.05, Kruskal-Wallis test, followed by Dunn's multiple comparison test with Bonferroni correction). (Figure modified from Biasella et al., 2020<sup>246</sup>).

#### 4.9.2 Effect of VTN\_rs704:C and VTN\_rs704:T on Deposition of ECM Structural Components

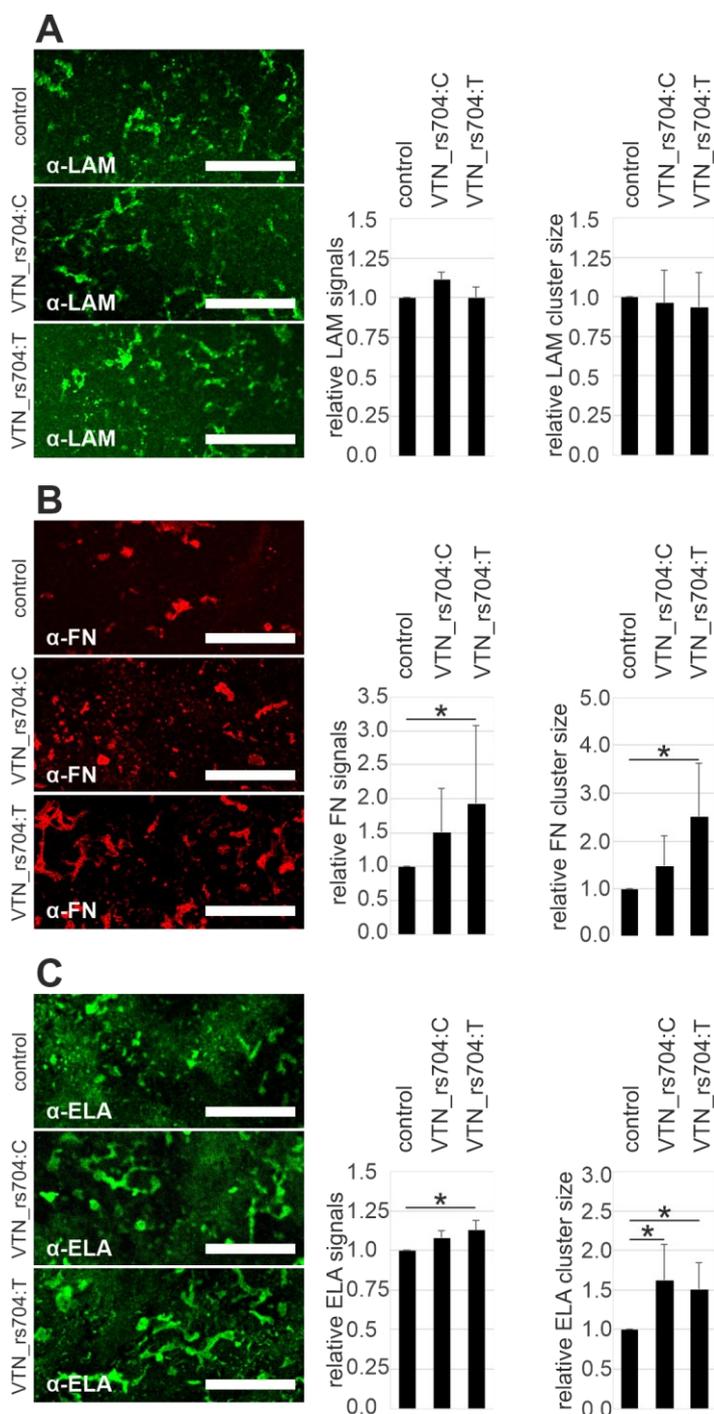

Next, an effect of VTN\_rs704:C and VTN\_rs704:T on the deposition and clustering of characteristic ECM structural components laminin, fibronectin, elastin, and collagen type V and VI<sup>282</sup> was analysed.

Laminin staining reflected disorganized fibers and aggregates in all ECMs analysed. The amount of laminin and its assembly were not affected by heterologous expression of the two vitronectin isoforms. Quantification of five independent experiments revealed a laminin signal intensity of  $1.11 \pm 0.16$  in VTN\_rs704:C-containing ECM and of  $1.00 \pm 0.05$  in VTN\_rs704:T-containing ECM, compared to control ECM. The cluster size of laminin was  $0.96 \pm 0.20$  in VTN\_rs704:C-containing ECM and  $0.93 \pm 0.21$  in VTN\_rs704:T-containing ECM, compared to control (**Figure 25A**).

Fibronectin appeared as densely packed aggregates in ECMs of non-vitronectin expressing cells. In ECMs containing vitronectin, these aggregates extended and formed fibers, with an increase in total fibronectin signal intensity. Both processes (fiber formation and total fibronectin deposition) appeared more pronounced in VTN\_rs704:T- than in VTN\_rs704:C-containing ECMs. i. e. quantification of five independent experiments revealed an increased fibronectin signal intensity of  $1.50 \pm 0.64$  in VTN\_rs704:C-containing ECMs, and of  $1.95 \pm 1.15$  in VTN\_rs704:T-containing ECMs, compared to control ( $p$  < 0.05 between VTN\_rs704:T and control; **Figure 25B**). In addition, the presence of vitronectin affected the size of fibronectin clusters, which increased to  $1.44 \pm 0.64$  in VTN\_rs704:C-containing ECMs and to

$2.50 \pm 1.12$  for VTN\_rs704:T-containing ECM ( $p < 0.05$  between VTN\_rs704:T and control; **Figure 25B**).

Elastin staining revealed a similar appearance than fibronectin staining: densely packed elastin aggregates were observed in ECMs of non-vitronectin expressing cells, while increased elastin deposition and fiber formation was observed in ECMs containing vitronectin. A quantification of five independent experiments revealed a slight increase in elastin signal intensity to  $1.08 \pm 0.05$  in VTN\_rs704:C-containing ECMs and to  $1.12 \pm 0.06$  in VTN\_rs704:T-containing ECMs, compared to control ( $p < 0.05$  between VTN\_rs704:T and control). Both vitronectin isoforms had a similar effect on elastin aggregation, leading to an increase in elastin cluster size to  $1.62 \pm 0.45$  in VTN\_rs704:C-containing ECMs and to  $1.51 \pm 0.34$  in VTN\_rs704:T-containing ECMs, compared to control ( $p < 0.05$  between both vitronectin isoforms and control; **Figure 25C**).

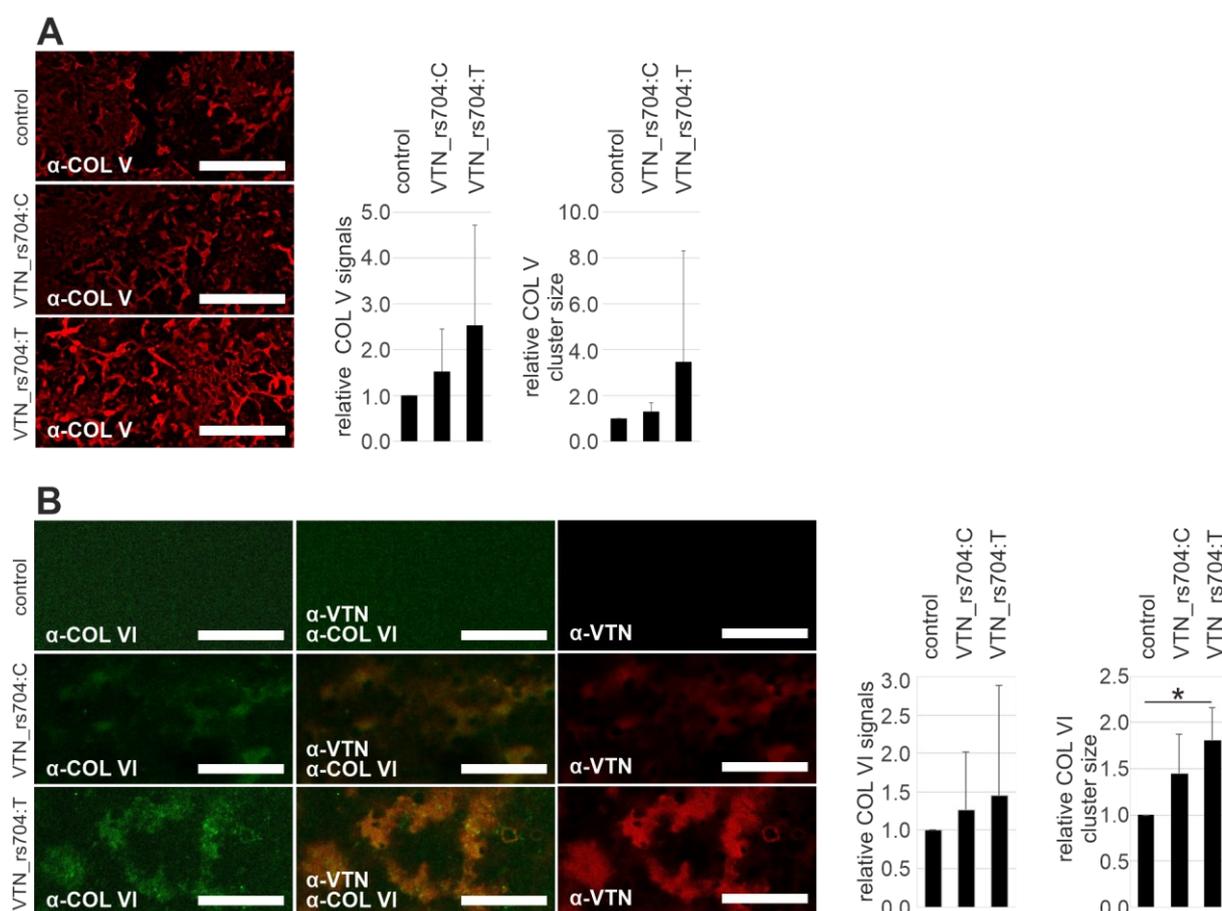

**Figure 25: Effect of VTN\_rs704:C and VTN\_rs704:T on deposition of laminin, fibronectin, and elastin into ARPE-19-deposited ECM.**

ARPE-19 cells transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T or with an empty control expression vector (pcDNA3.1) were incubated for 4 weeks on Transwell filters. After 4 weeks, the inserts were decellularized and subjected to immunostaining with antibodies against (A) laminin (α-LAM), (B) fibronectin (α-FN), and (C) elastin (α-ELA). Confocal microscopy images were taken at 10× magnification. Scale bars: 100 μm. Fluorescence intensity and average cluster size were measured using ImageJ. Data represent the mean ± SD of five biological replicates calibrated against the control. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal–Wallis test, followed by Dunn's multiple comparison test with Bonferroni correction). (Figure modified from Biasella et al., 2020<sup>246</sup>).

Staining of collagen V revealed fibers in all ECMs analysed. Quantification of five independent experiments demonstrated a signal intensity for collagen V tendentially higher in ECMs containing vitronectin (VTN\_rs704:C:  $1.52 \pm 0.92$ , VTN\_rs704:T:  $2.53 \pm 2.18$ , compared to control,  $p > 0.05$ , **Figure 26A**). The analysis of cluster size also showed a slight effect of the presence of VTN\_rs704:C and VTN\_rs704:T, with both isoforms tendentially increasing collagen V clustering (VTN\_rs704:C:  $1.29 \pm 0.38$ , VTN\_rs704:T:  $3.46 \pm 4.84$ , compared to control,  $p > 0.05$ , **Figure 26A**).

Immunolabelling of collagen VI revealed an ECM deposition but without prominent cluster or fiber formation (**Figure 26B**). In vitronectin-containing ECM, a notable increase of collagen VI clustering was observed. Although quantification of six independent experiments failed to show a statistically significant increase in total collagen VI signal intensity, collagen VI cluster size was strongly affected. Again, VTN\_rs704:T exerted a stronger effect than VTN\_rs704:C ( $1.45 \pm 0.42$  for VTN\_rs704:C-containing ECMs and  $1.81 \pm 0.35$  for VTN\_rs704:T-containing ECMs compared to control;  $p < 0.05$  between VTN\_rs704:T and control; **Figure 26B**). Interestingly, co-immunolabelling of collagen VI and vitronectin showed an almost identical distribution pattern, suggesting a possible interaction between both components (**Figure 26B**).

**Figure 26: Effect of VTN\_rs704:C and VTN\_rs704:T on deposition of collagens into ARPE-19-deposited ECM.** ARPE-19 cells transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T or with an empty control expression vector (pcDNA3.1) were incubated for 4 weeks on Transwell filters. After 4 weeks, the inserts were decellularized and subjected to immunostaining with antibodies against (A) collagen V ( $\alpha$ -COL V) and (B) collagen VI ( $\alpha$ -COL VI). Merged picture showed co-stained collagen VI and vitronectin ( $\alpha$ -VTN) (B). Confocal microscopy images were taken at  $10\times$  magnification. Scale bars: 100  $\mu$ m. Fluorescence intensity and average cluster size were measured using ImageJ. Data represent the mean  $\pm$  SD of five (collagen V) and six (collagen VI) biological replicates calibrated against the control. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test with Bonferroni correction). (Figure B modified from Biasella et al., 2020<sup>246</sup>).

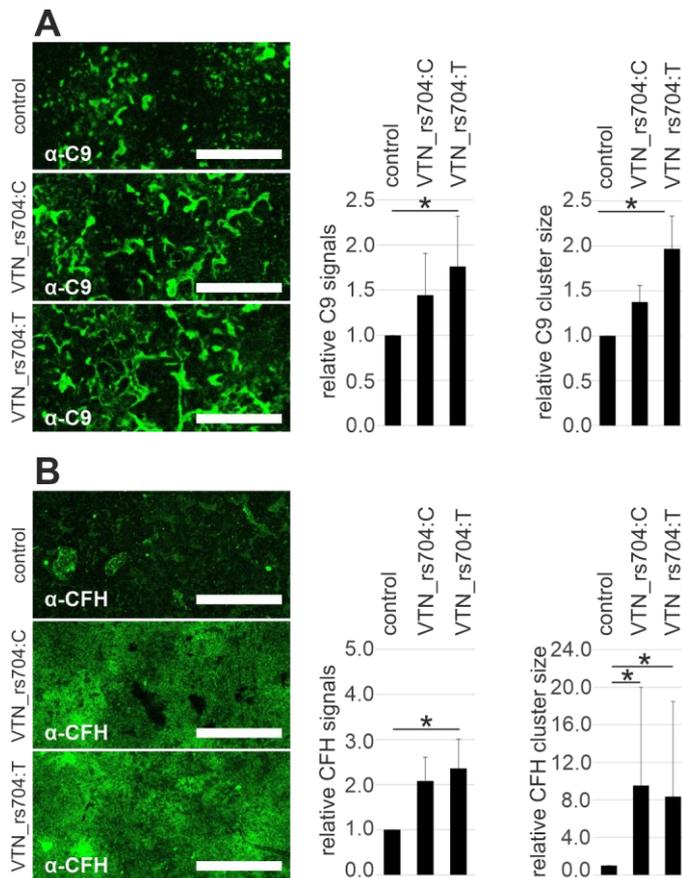

### 4.9.3 Effect of VTN\_rs704:C and VTN\_rs704:T on Deposition of ECM Functional Components

Next, the effect of VTN\_rs704:C and VTN\_rs704:T on the deposition of functional components known to be part of the ECM and shown to be associated with AMD aetiology, like complement factors C9 and CFH<sup>283,284</sup>, TIMP3<sup>95,285</sup>, and VEGF<sup>58,286</sup> were analysed.

#### 4.9.3.1 Effect of VTN\_rs704:C and VTN\_rs704:T on ECM Deposition of Complement Factors

C9 appeared as densely packed aggregates in the ECM. The analysis of five independent experiments showed that the presence of vitronectin in these matrices was correlated with increased C9 signal intensity ( $1.44 \pm 0.46$  for VTN\_rs704:C and  $1.76 \pm 0.56$  for VTN\_rs704:T compared to control;  $p < 0.05$  between VTN\_rs704:T and control; **Figure 27A**). In addition, C9 aggregates showed a notable increase in size towards vitronectin with a more pronounced effect in the presence of VTN\_rs704:T ( $1.38 \pm 0.18$  in VTN\_rs704:C-containing ECMs, and  $1.97 \pm 0.36$  in VTN\_rs704:T-containing ECMs, compared to control;  $p < 0.05$ ) between VTN\_rs704:T and control; **Figure 27A**).

In contrast to C9, CFH was more evenly distributed along the ECM without prominent fiber formation. Again, the analysis of five independent experiments showed that vitronectin protein expression was associated with increased CFH signal intensity ( $2.08 \pm 0.52$  in VTN\_rs704:C-containing ECMs and  $2.35 \pm 0.65$  in VTN\_rs704:T-containing ECMs, compared to control;  $p < 0.05$  between VTN\_rs704:T and control; **Figure 27B**). In vitronectin-containing matrices, CFH formed a meshwork with an observable increase in CFH aggregation ( $9.53 \pm 10.48$  -fold in VTN\_rs704:C-containing ECMs and  $8.35 \pm 10.13$ -fold in VTN\_rs704:T-containing ECMs, compared to control;  $p < 0.05$  between VTN\_rs704:C as well as between VTN\_rs704:T and control; **Figure 27B**).

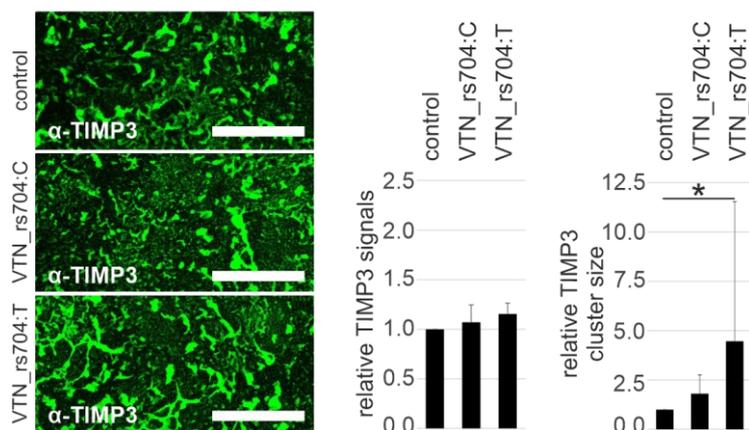

**Figure 27: Effect of VTN\_rs704:C and VTN\_rs704:T on deposition of complement factors C9 and CFH into ARPE-19-deposited ECM.**

ARPE-19 cells transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T or with an empty control expression vector (pcDNA3.1) were incubated for 4 weeks on Transwell filters. After 4 weeks, the inserts were decellularized and subjected to immunostaining with antibodies against (A) complement component 9 ( $\alpha$ -C9) and (B) complement factor H ( $\alpha$ -CFH). Confocal microscopy images were taken at 10 $\times$  magnification. Scale bars: 100  $\mu$ m. Fluorescence intensity and average cluster size were measured using ImageJ. Data represent the mean  $\pm$  SD of five biological replicates calibrated against the control. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test with Bonferroni correction).

#### 4.9.3.2 Effect of VTN\_rs704:C and VTN\_rs704:T on ECM Deposition of TIMP3

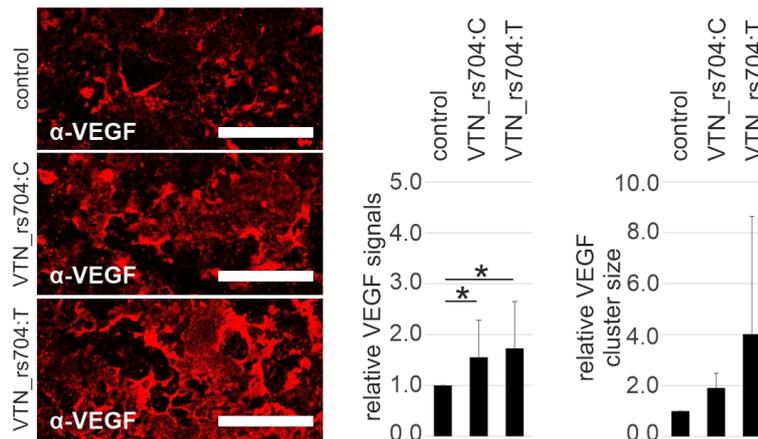

Quantification of six independent experiments showed that the signal intensity and thus the total amount of deposited TIMP3 was unaffected by the presence of vitronectin ( $1.07 \pm 0.17$  in VTN\_rs704:C-containing ECMs, and  $1.15 \pm 0.11$  in VTN\_rs704:T-containing ECMs, compared to control). In contrast, the size of TIMP3 aggregates was more prominent in the presence of VTN\_rs704:T ( $1.81 \pm 0.94$  in VTN\_rs704:C-containing ECMs and  $4.46 \pm 7.08$  in VTN\_rs704:T-containing ECMs, compared to control;  $p < 0.05$  between VTN\_rs704:T and control; **Figure 28**).

**Figure 28: Effect of VTN\_rs704:C and VTN\_rs704:T on deposition of TIMP3 into ARPE-19-deposited ECM.** ARPE-19 cells transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T or with an empty control expression vector (pcDNA3.1) were incubated for 4 weeks on Transwell filters. After 4 weeks, the inserts were decellularized and subjected to immunostaining with antibodies against tissue inhibitor of metalloproteinase 3 ( $\alpha$ -TIMP3). Confocal microscopy images were taken at 10 $\times$  magnification. Scale bars: 100  $\mu$ m. Fluorescence intensity and average cluster size were measured using ImageJ. Data represent the mean  $\pm$  SD of six biological replicates calibrated against the control. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test with Bonferroni correction).

#### 4.9.3.3 Effect of VTN\_rs704:C and VTN\_rs704:T on ECM Deposition of VEGF

Finally, an effect of VTN\_rs704:C and VTN\_rs704:T on VEGF deposition was investigated in the ECMs produced by ARPE-19 cells heterologously expressing VTN\_rs704:C or VTN\_rs704:T. Quantification of six independent experiments showed a significant increase in VEGF signal intensity in vitronectin-containing ECMs compared to vitronectin-free ECMs ( $1.55 \pm 0.73$  with VTN\_rs704:C and  $1.73 \pm 0.92$  with VTN\_rs704:T compared to control;  $p < 0.05$  between VTN\_rs704:C as well as between VTN\_rs704:T and control; **Figure 29**). The presence of vitronectin also seemed to increase VEGF aggregation ( $1.91 \pm 0.57$  for VTN\_rs704:C and  $4.02 \pm 4.62$  for VTN\_rs704:T compared to control;  $p > 0.05$  between all replicates; **Figure 29**).

**Figure 29: Effect of VTN\_rs704:C and VTN\_rs704:T on deposition of VEGF into ARPE-19-deposited ECM.**

ARPE-19 cells transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T or with an empty control expression vector (pcDNA3.1) were incubated for 4 weeks on Transwell filters. After 4 weeks, the inserts were decellularized and subjected to immunostaining with antibodies against vascular endothelial growth factor ( $\alpha$ -VEGF). Confocal microscopy images were taken at 10 $\times$  magnification. Scale bars: 100  $\mu$ m. Fluorescence intensity and average cluster size were measured using ImageJ. Data represent the mean  $\pm$  SD of six biological replicates calibrated against the control. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test with Bonferroni correction).

#### 4.10 Interaction of VTN\_rs704:C and VTN\_rs704:T with PAI-1

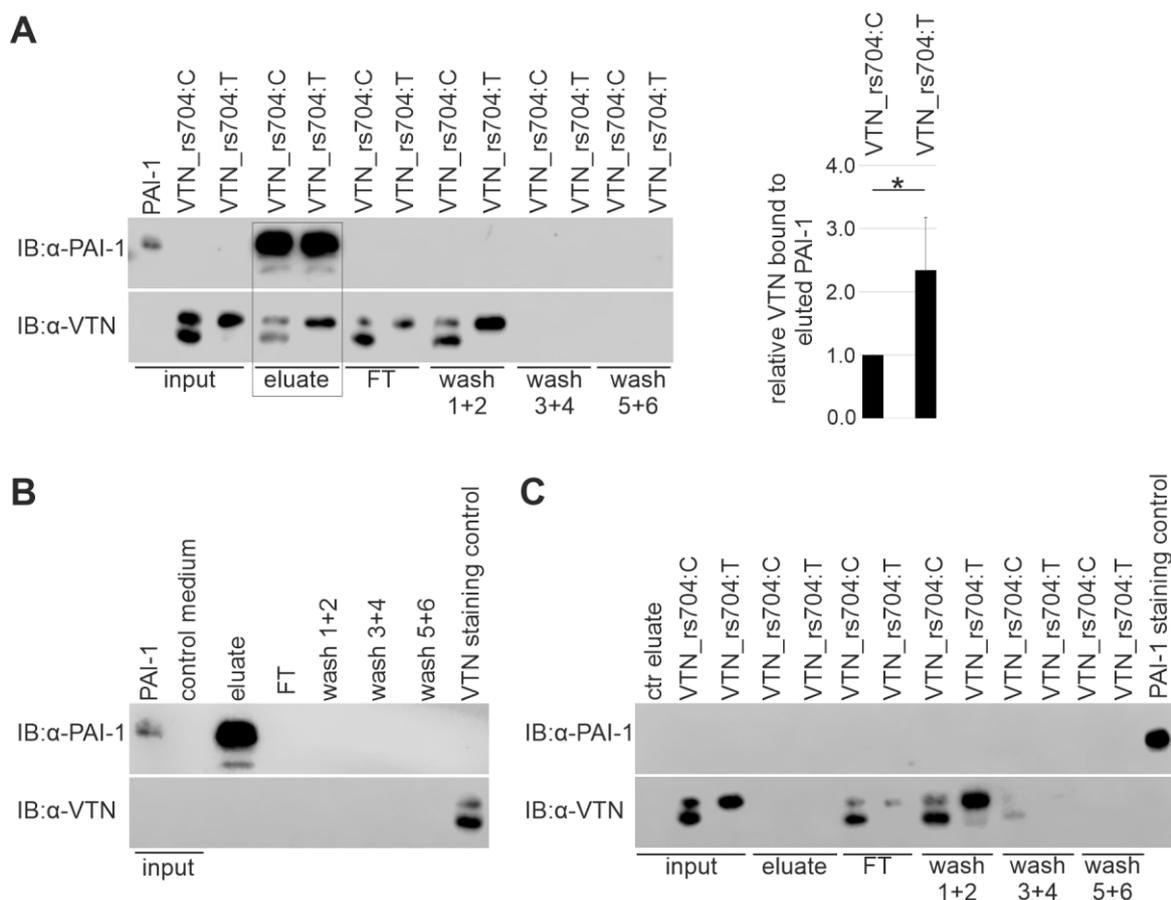

The interaction of vitronectin with PAI-1 is well characterised<sup>185,287,288</sup>. Of interest, PAI-1 has been implicated in neovascular AMD<sup>289-291</sup>.

##### 4.10.1 Influence of rs704 on Vitronectin Capacity to Bind PAI-1

Differences between VTN\_rs704:C and VTN\_rs704:T in their respective ability to bind PAI-1 were investigated using affinity chromatography. After immobilization of Strep-tagged PAI-1 onto gravity flow columns, medium containing VTN\_rs704:C and VTN\_rs704:T heterologously expressed by HEK293-EBNA cells, or vitronectin-free control medium was loaded onto the columns. After intensive washing, elution of PAI-1 (and thus co-elution of PAI-1 bound proteins) was performed. Western blot analysis demonstrated the presence of both vitronectin isoforms in the elution fractions (**Figure 30A**, eluted fractions highlighted in black rectangle), and thus effective binding of both VTN\_rs704:C and VTN\_rs704:T to PAI-1. Interestingly, densitometric quantification of five independent experiments revealed higher levels of VTN\_rs704:T in the eluted PAI-1 fraction compared to VTN\_rs704:C ( $2.28 \pm 0.81$ -fold increase,  $p < 0.05$ ; **Figure 30A**), suggesting a potential influence of rs704 on the ability of vitronectin to bind PAI-1.

As a negative control, input without vitronectin was loaded onto columns coupled with PAI-1 and subjected to the identical experimental procedure described for vitronectin-containing input (**Figure 30B**). In this experiment, no vitronectin staining was observed in any of the fractions analysed. An additional control experiment without immobilised PAI-1 failed to detect vitronectin signals in the elution fraction. Instead, vitronectin was found predominantly

in the flow through and wash fractions (**Figure 30C**), excluding unspecific binding of vitronectin isoforms to the column material.

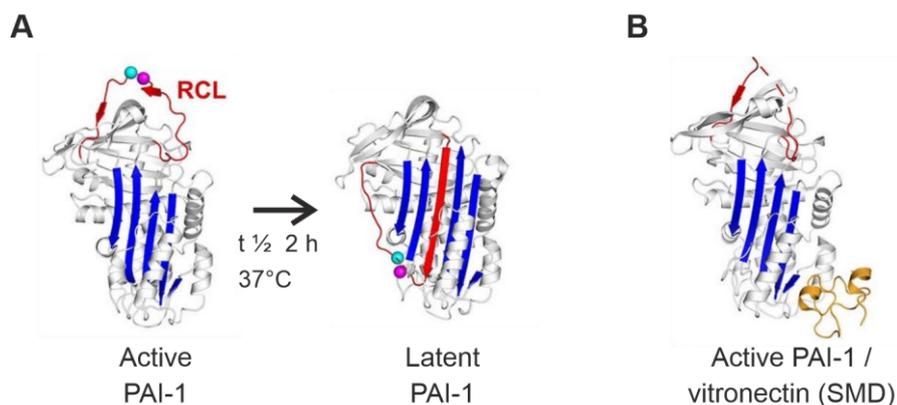

**Figure 30: Effect of rs704 on the capacity of vitronectin to bind PAI-1.**

(A) PAI-1-coupled affinity chromatography columns (input) were loaded with medium containing untagged VTN\_rs704:C or VTN\_rs704:T (input). After several washing steps, proteins were eluted ('eluate') and subjected to immunoblot (IB) analysis with antibodies against vitronectin (α-VTN) and PAI-1 (α-PAI-1). Also shown are flow through (FT) and wash fractions (wash) obtained prior to PAI-1 elution. After densitometric quantification, vitronectin signals in the eluate were normalised for the respective inputs and eluted PAI-1. Data represent the mean ± SD of five replicates, calibrated against VTN\_rs704:C. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Mann-Whitney U test). (B) Control medium without vitronectin loaded onto PAI-1-coupled columns and subjected to the identical experimental procedure described in (A). (C) Non-specific binding of vitronectin to column material tested by loading medium containing untagged vitronectin (input) onto columns without PAI-1 (coupled with empty control eluate) and subjected to the identical experimental procedure as in (A). (Figure modified from Biasella et al., 2022<sup>292</sup>).

#### 4.10.2 Influence of VTN\_rs704:C and VTN\_rs704:T on Preserving PAI-1 Activity

Under physiological conditions, PAI-1 spontaneously converts from the enzymatically active state to an energetically more favourable but non-functional (latent) conformation with a half-life of ~2 h. The process involves the internal translocation of the reactive centre loop (**Figure 31A**), which is responsible for the initial interaction of PAI-1 with uPA<sup>226</sup>. Through allosteric regulation, vitronectin stabilises the active state of PAI-1 by hindering the insertion of its reactive centre loop<sup>226</sup> (**Figure 31B**).

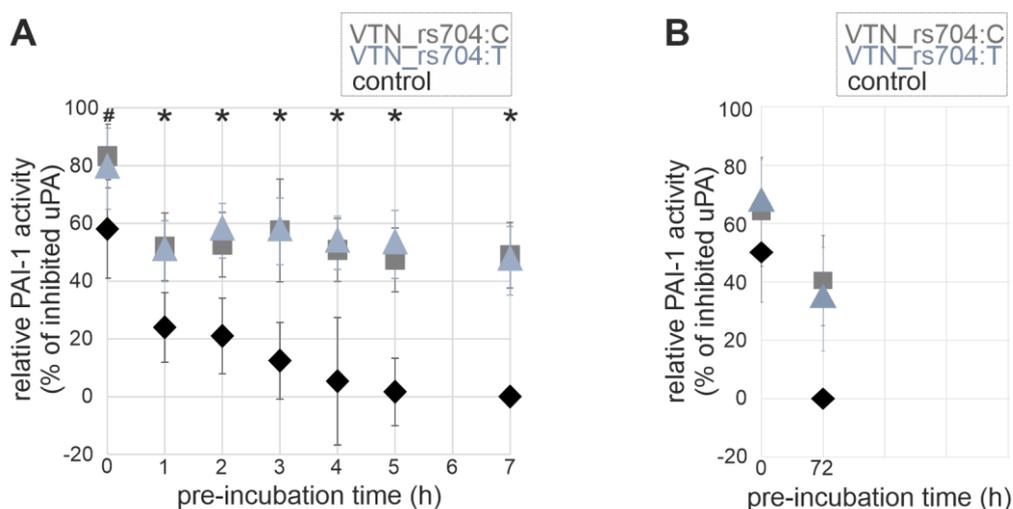

**Figure 31: Schematic overview of PAI-1 functional states.**

(A) PAI-1 spontaneously converts from the active to the latent form with a half-life ( $t^{1/2}$ ) of  $\sim 2$  h at  $37^{\circ}\text{C}$ . During this transition the reactive centre loop (RCL) of PAI-1 (shown in red) is translocated within the central  $\beta$ -sheet (in blue) of the PAI-1 molecule. (B) The somatomedin domain (SMD) of vitronectin (shown in orange) binds to PAI-1 and prevents the internalisation of its RCL by stabilising its active state. (Figure modified from Sillen and Declerck, 2020<sup>226</sup>).

On this basis, the consequence of rs704 on the ability of vitronectin stabilise PAI-1 was examined *via* the cell-free PAI-1 activity assay. This assay assesses the inhibitory effect of PAI-1 on the proteolytic activity of its target protease uPA<sup>226,293</sup>, which in turn cleaves a chromogenic substrate. To allow stabilization of active PAI-1 by the two vitronectin isoforms, PAI-1 was pre-incubated with VTN\_rs704:C, VTN\_rs704:T, or control eluate, for 0, 1, 2, 3, 4, 5, and 7 h. After pre-incubation, aliquots from the mixture of PAI-1 with vitronectin or with control eluate were subjected to the PAI-1 activity assay applying an incubation time of 2.5 h. Quantification of six independent experiments showed that both VTN\_rs704:C and VTN\_rs704:T similarly stabilised enzymatically active PAI-1, and thus increased PAI-1-induced uPA inhibition. A stabilizing effect was already observed after 0 h of pre-incubation (uPA inhibition by PAI-1 at 0 h:  $83\% \pm 11\%$  in the presence of VTN\_rs704:C,  $79\% \pm 14\%$  in the presence of VTN\_rs704:T,  $58\% \pm 17\%$  in the presence of control eluate,  $p < 0.05$  between VTN\_rs704:C and control, **Figure 32A**) likely due to a stabilising effect of the vitronectin during the 2.5 h of incubation required for the enzymatic reaction in the assay (see above). From 1 to 7 h of pre-incubation, both vitronectin isoforms showed a similar capacity to stabilize PAI-1. The stabilising effect of vitronectin on PAI-1 was still effective after 7 h of pre-incubation (uPA inhibition by PAI-1 at 7 h:  $49\% \pm 11\%$  in the presence of VTN\_rs704:C and  $47\% \pm 12\%$  in the presence of VTN\_rs704:T compared to 0% in the presence of control eluate;  $p < 0.05$  between control and VTN\_rs704:C or VTN\_rs704:T; **Figure 32A**). In contrast, PAI-1 incubated with control eluate showed a strong and time-dependent decrease in its ability to inhibit uPA (uPA inhibition by PAI-1 decreasing from around 25% at 1 h of pre-incubation to 0% at 7 h of pre-incubation, **Figure 32A**). Similar results were obtained in an independent experiment to test the activity of PAI-1 isoforms upon long term pre-incubation with PAI-1: The stabilising effect on PAI-1 active state by vitronectin was still visible after 72 h, again without any differences between the two isoforms

(uPA inhibition by PAI-1 at 72 h: 40%  $\pm$  15% in the presence of VTN\_rs704:C and 34%  $\pm$  18% in the presence of VTN\_rs704:T compared to 0% in the presence of control eluate) (**Figure 32B**).

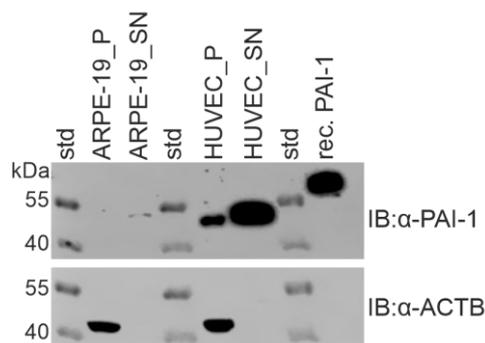

**Figure 32: Effect of rs704 on the capacity of vitronectin to maintain PAI-1 active state.**

VTN\_rs704:C (grey squares), VTN\_rs704:T (ice-blue triangles), or control eluate (control, black diamonds) were mixed with PAI-1 and incubated at 37°C. Aliquots of vitronectin/PAI-1 or control eluate/PAI-1 mixtures were subjected to the PAI-1 activity assay after 0, 1, 2, 3, 4, 5 and 7 h (**A**), or after 0 and 72 h (**B**) of pre-incubation. The PAI-1-dependent uPA activity was measured after 2.5 h of further incubation required for the enzymatic reaction. The data were calibrated against the values obtained for control measurements at 7 h (**A**) and at 72h (**B**) (uPA at its maximum activity in our experimental setting, 100%). To better visualize the extent of PAI-1 inhibition (and thus the inhibitory capacity of PAI-1), the calibrated uPA activity was subtracted from 100 % (maximal uPA activity). Data represent the mean  $\pm$  SD of six replicates (**A**) and of three replicates (**B**). Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test with Bonferroni correction) between VTN\_rs704:C as well as VTN\_rs704:T and control. Hash character (#) indicates statistically significant difference ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test with Bonferroni correction) between VTN\_rs704:C and control. (Figure modified from Biasella et al., 2022<sup>292</sup>).

#### 4.10.3 Effect of VTN\_rs704:C and VTN\_rs704:T on PAI-1 Expression

In this final project, the influence of rs704 on the capacity of vitronectin to affect PAI-1 expression and/or extracellular deposition was assessed in cultured endothelial and RPE cells.

Prior to these analyses, endogenous PAI-1 protein expression was determined in ARPE-19 cells and HUVECs. Western Blot analyses of ARPE-19 and HUVEC lysates revealed endogenous PAI-1 expression in both cell types. Specifically, PAI-1 was detected as a molecular weight species of approximately 50kDa corresponding to its glycosylated form<sup>252,253</sup>. In ARPE-19 cells, PAI-1 expression was weak compared to HUVECs: while no or only very faint signals were visible in the cell fraction of ARPE-19 cells, weak PAI-1 signals were visible in the culture medium of ARPE-19 cells. In contrast, a considerable amount of PAI-1 was detected in both cell lysates and culture medium of HUVECs (**Figure 33**).

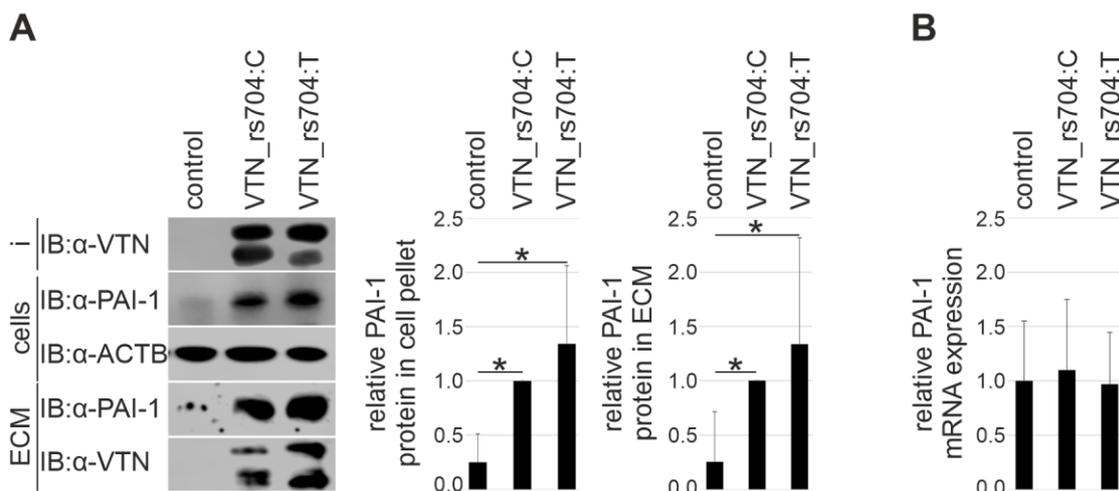

**Figure 33: Endogenous PAI-1 protein expression in ARPE-19 cells and HUVECs.**

Cells seeded on 6-well plates were cultured for 24 h. Endogenous PAI-1 (of about 50-54 kDa in its glycosylated form) was detected after western blot analysis of cell lysates (P) and culture medium (supernatant, SN) using antibodies against PAI-1. The ACTB immunoblot served as a loading control. Purified, Strep-tagged PAI-1 (50-54 kDa for glycosylated PAI-1 plus 5.1 kDa for Strep-tag) was loaded as a positive control.

#### 4.10.3.1 PAI-1 Expression and Deposition into the ECM by HUVECs Exposed to Recombinant VTN\_rs704:C and VTN\_rs704:T

HUVECs were treated with purified recombinant VTN\_rs704:C, VTN\_rs704:T, or control eluate and incubated for 24 h at 37°C. After treatment, cells and ECM were harvested and subjected to western blot analysis with antibodies against PAI-1, vitronectin and ACTB (loading control). Quantification of nine independent experiments revealed an approximately 4-fold higher concentration of endogenous PAI-1 when cells were exposed to the two vitronectin isoforms in comparison to cells treated with control eluate ( $0.25 \pm 0.26$  with control eluate,  $1.35 \pm 0.72$  with VTN\_rs704:T, compared to VTN\_rs704:C-treated cells,  $p < 0.05$  between control and both vitronectin isoforms; **Figure 34A**). Concurrent with a precipitation of both VTN\_rs704:C and VTN\_rs704:T into the ECM (**Figure 34A**), an approximately 4-fold higher accumulation of PAI-1 was observed in the ECM of vitronectin-treated cells compared to cells treated with control eluate ( $0.26 \pm 0.46$  with control eluate,  $1.34 \pm 0.98$  with VTN\_rs704:T, compared to VTN\_rs704:C-treated cells,  $p < 0.05$  between control and both vitronectin isoforms; **Figure 34A**).

To investigate whether the enhancing effect of the two vitronectin isoforms on endogenous PAI-1 levels was a consequence of increased *PAI-1* gene expression, HUVECs were treated with VTN\_rs704:C, VTN\_rs704:T, or control eluate and incubated for 24 h at 37°C. After 24 h, RNA was isolated and *PAI-1* transcription was tested by qRT-PCR. Quantification of six independent experiments revealed no differences in *PAI-1* expression between cells treated with VTN\_rs704:C, VTN\_rs704:T, or control eluate (**Figure 34B**), and thus no effect of VTN\_rs704:C and VTN\_rs704:T on *PAI-1* mRNA expression.

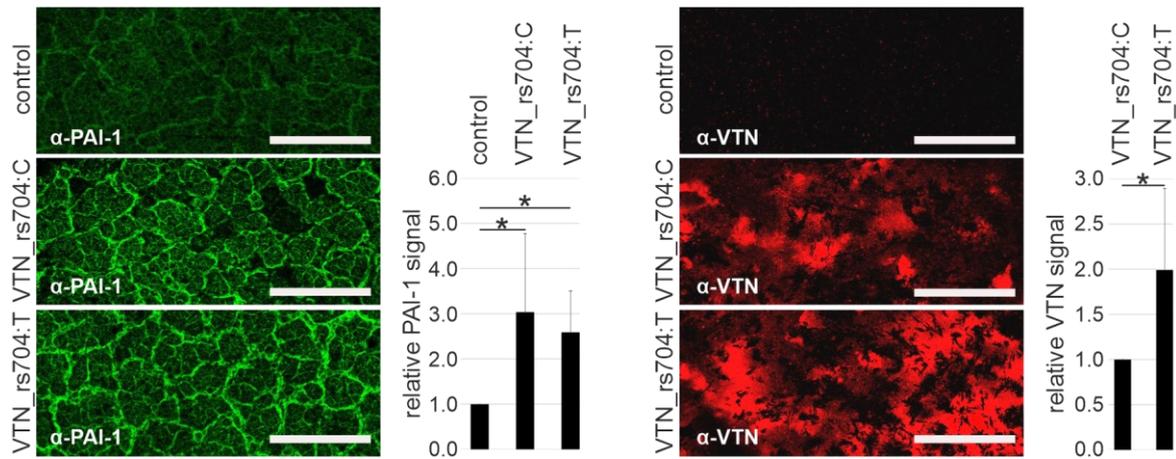

**Figure 34: Effect of VTN\_rs704:C and VTN\_rs704:T on endogenous endothelial PAI-1 protein expression and ECM deposition.**

HUVECs were incubated for 24 h with input (i) including purified VTN\_rs704:C, VTN\_rs704:T, or same volume of control eluate (control), respectively. **(A)** Input, cells and ECMs were subjected to immunoblot (IB) analysis with antibodies against vitronectin, PAI-1 and ACTB. PAI-1 signals were densitometrically quantified and normalized against ACTB. Data represent the mean  $\pm$  SD of nine biological replicates, calibrated against the PAI-1 signals obtained after VTN\_rs704:C addition. Asterisks (\*) indicate statistically significant differences ( $p < 0.05$ , Kruskal-Wallis test, followed by Dunn's multiple comparison test with Bonferroni correction). **(B)** mRNA was isolated and PAI-1 expression determined by qRT-PCR. Data represent the mean  $\pm$  SD of six biological replicates, calibrated against the control. (Figure modified from Biasella et al., 2022<sup>292</sup>).

#### 4.10.3.2 PAI-1 Deposition into the ECM by ARPE-19 Cells Heterologously Expressing VTN\_rs704:C and VTN\_rs704:T

ARPE-19 cells were transfected with expression vectors for VTN\_rs704:C, VTN\_rs704:T, or with a control expression vector. After 24 h, transfected cells were transferred onto Transwell filters and cultivated for 8 weeks. After 8 weeks, the cells were removed from the filters and the deposited ECM was analysed by immunolabelling of PAI-1 and vitronectin. Both VTN\_rs704:C- and VTN\_rs704:T-treated cells show an increasing effect on PAI-1 deposition in the ECM. Specifically, quantification of four independent experiments showed an approximately 3-fold increase in PAI-1 protein deposition in the vitronectin-containing ECMs compared to the vitronectin-free control matrixes ( $3.03 \pm 1.73$  with VTN\_rs704:C,  $2.59 \pm 0.91$  with VTN\_rs704:T, compared to control;  $p < 0.05$  between control and VTN\_rs704:C or VTN\_rs704:T; **Figure 35**). In addition, as observed in the ECM deposited by ARPE-19 cells after 4 weeks of cultivation (see section 4.9.1), a stronger deposition of VTN\_rs704:T compared to VTN\_rs704:C ( $1.99 \pm 0.90$ -fold increased intensity of VTN\_rs704:T compared to VTN\_rs704:C;  $p < 0.05$ ; **Figure 35**) was detected in the ECM deposited by transfected ARPE-19 after 8 weeks of cultivation.

**Figure 35: Effect of VTN\_rs704:C and VTN\_rs704:T on deposition of PAI-1 into ARPE-19-deposited ECM.**

ARPE-19 cells transfected with expression vectors for VTN\_rs704:C or VTN\_rs704:T or with an empty control expression vector (pcDNA3.1) were incubated for 8 weeks on Transwell filters. After 8 weeks, the inserts were decellularized and subjected to immunostaining with antibodies against plasminogen activator inhibitor 1 ( $\alpha$ -PAI-1) and vitronectin ( $\alpha$ -VTN). Confocal microscopy images were taken at 10 $\times$  magnification. Scale bars: 100  $\mu$ m. Fluorescence intensities were measured using ImageJ. Data represent the mean  $\pm$  SD of four independent replicates, calibrated against VTN\_rs704:C (for vitronectin signals) or control (for PAI-1 signals). Asterisks (\*) indicate statistically significant differences (\* $p$  < 0.05, Mann-Whitney U test for VTN;  $p$  < 0.05, Kruskal-Wallis test for PAI-1, followed by Dunn's multiple comparison test with Bonferroni correction). (Figure modified from Biasella et al., 2022<sup>292</sup>).

## 5. Discussion

The incomplete understanding of the complex mechanisms causing AMD makes this common retinal disorder the leading cause of incurable blindness worldwide, along with social distress and negative impact on mental health due to its disabling effects on individual autonomy<sup>294,295</sup>. To contribute to a better understanding of the pathobiology of AMD, this doctoral thesis explored the functional significance of the statistical association of rs704 within the coding sequences of the *VTN* gene with AMD. The study presents evidence that this polymorphism significantly alters the expression of the encoded vitronectin protein, as well as vitronectin processing, secretion, and ability to bind retinal and endothelial cells. Functional investigations revealed a similar capacities of the non-AMD risk-associated VTN\_rs704:C and AMD risk-associated VTN\_rs704:T isoforms to regulate RPE cell adhesion and activation of the intracellular ERK signalling pathway. In endothelial cells, both isoforms decreased adhesion and tubulogenesis, while only the non-risk-associated isoform slightly reduced migration. Heterologous vitronectin expression in ARPE-19 cells increased ECM deposition and clustering of structural ECM constituents (e.g., fibronectin, elastin, collagen VI), as well as deposition of VEGF and complement factors (e.g., C9 and CFH), with the risk-associated isoform showing a greater effect on these parameters. Finally, exposure of RPE and endothelial cells to VTN\_rs704:C and VTN\_rs704:T enhanced expression and ECM deposition of PAI-1, a potent angiogenic regulator already implicated in AMD pathology<sup>289-291</sup>. While the risk-associated isoform exhibited a stronger binding to PAI-1, both isoforms equally maintained the active state of PAI-1. Taken together, this study suggests a close functional link between rs704 and vitronectin with functional consequences possibly for the pathogenesis of AMD.

### 5.1 AMD-associated rs704 Affects Vitronectin Expression

Polymorphisms in or around genes can affect transcription or mRNA stability, for example, by disrupting or generating binding sites for transcription factors, or altering mRNA stability<sup>296,297</sup>. Aberrant mRNA expression can be causal for disease development, as in cardiac laminopathy, where a missense mutation in the *LMNA* gene by altering the splicing process causes nonsense-mediated mRNA decay and reduced expression of lamin, an architectural protein of the cell nucleus, leading to arrhythmic disturbances and severe cardiomyopathy<sup>298</sup>. Here, semi-quantitative sequencing of vitronectin cDNA from hiPSC-RPE cells and human retinal tissues heterozygous for rs704 revealed no effect of this polymorphism on *VTN* transcriptional activity. These results are consistent with data from the Genotype-Tissue Expression (GTEx) project, which revealed no effect of rs704 on vitronectin mRNA expression in 49 different (non-retinal) healthy tissues (e.g., whole blood, arterial tissue, and brain tissue) from 838 post-mortem donors<sup>299</sup>.

In contrast, heterologous vitronectin expression revealed a significant effect of rs704 on vitronectin protein expression and secretion, in specific a strong increase in protein levels of the AMD risk-associated VTN\_rs704:T isoform compared to the non-AMD-associated VTN\_rs704:C. In line with these experiments, an increase in vitronectin plasma levels was described to be associated with the rs704 risk variant in a large human plasma proteome analysis including 3,301 healthy participants <sup>243</sup>. Consequently, rs704 was classified as a pQTL <sup>243</sup>. The mechanism by which rs704 affects protein quantity of vitronectin were not investigated within this study but may be explained, for example, by codon usage bias (the preference for certain synonymous codons), which can influence translation kinetics <sup>300,301</sup>. The methionine encoding triplet codon AUG (adenine–uracil–guanine, found in the risk allele) has a higher frequency than the threonine encoding triplet codon ACG (adenine–cytosine–guanine, found in the non-risk allele), specifically 22.3 in 1000 compared to 6.2 in 1000 <sup>302</sup>. As frequent codons have a higher abundance of their corresponding tRNA <sup>300,301</sup>, the higher availability of the AUG codon tRNA could therefore lead to an increased translation of VTN\_rs704:T resulting in increased protein levels. Similarly, in a study on the expression of the small GTPase KRas protein, the progressive replacement of rare codons with common codons led to increases in KRas expression at both transcriptional and translational levels <sup>303</sup>. Furthermore, protein folding was shown to be affected by translation kinetics <sup>304</sup>. Moreover, rs704:C>T induces an exchange from a polar (threonine) to an unpolar amino acid (methionine) in vitronectin. Thus, alterations in translation velocity or amino acid composition could affect protein folding and translocation from the endoplasmic reticulum to the Golgi apparatus or protein retention in the Golgi <sup>305,306</sup>. For example, the rs704-dependent amino acid exchange may affect the ability of vitronectin to interact with lipids and phospholipids in the Golgi bilayer, resulting in an altered escape from the Golgi vesicles. A similar scenario has been reported as a consequence of missense mutations within the N-terminal transmembrane domain of the protein GlcNAc-1-phosphotransferase <sup>307</sup>. Alternatively, increased protein levels of VTN\_rs704:T might be a consequence of changes in protein stability. The effect of rs704 on vitronectin folding and processing was described before <sup>237,238</sup> and could affect the susceptibility of the protein for degrading enzymes or stress-induced denaturation, as observed in the case of arrhythmogenic right ventricular cardiomyopathy (ARVC), where the C796R missense mutation dramatically affects the folding of the plakophilin-2 (PKP2) protein, a component of the cardiac desmosome, resulting in altered proteolytic degradation by calpain proteases and thus in the amount of PKP2 <sup>308</sup>.

## 5.2 AMD-associated rs704 Affects Vitronectin Processing

After heterologous expression, the non-AMD risk-associated isoform VTN\_rs704:C appeared as a mixture of single and cleaved forms, while the AMD risk-associated VTN\_rs704:T isoform was less susceptible to proteolytic cleavage and was expressed predominantly in its

intact single-chain form. These results confirm previous findings reporting a correlation between plasma vitronectin processing and rs704-induced amino acid exchange T400M<sup>237,238</sup>. Further analysis of vitronectin processing revealed that the difference in the susceptibility to endoproteolytic cleavage of the two vitronectin isoforms is limited to furin-mediated proteolysis, while plasmin-mediated proteolysis at aa 380 was not affected. Although the amino acid change caused by rs704 in aa 400 does not disrupt the furin recognition sequence (RXXR, furin minimal consensus motif)<sup>309</sup> involving aa 395-398, it is localized only 2 amino acid residues apart. It might thus trigger conformational changes in its vicinity that mask the furin recognition sequence, which could result in the observed reduced cleavage of VTN\_rs704:T by furin. In consistence with this assumption, Chain and colleagues observed that rs704 induces structural rearrangements in vitronectin. Specifically, they showed that protein kinase A phosphorylates the single-chain but not the two-chain form of vitronectin, due to burial and inaccessibility of the phosphorylation site in the cleaved, two-chain form of the protein<sup>239,241</sup>. In contrast, the plasmin cleavage site is located at aa 380<sup>257</sup> and is obviously not affected by the rs704-mediated amino acid change and/or associated structural changes. In agreement with this, no effect of rs704 on the stability and multimerization of vitronectin was observed, which would indicate that the two vitronectin isoforms share similar biophysical properties. However, a detailed analysis of sequence variability by high-resolution techniques, such as nuclear magnetic resonance<sup>310</sup>, or biophysical analyses such as circular dichroism<sup>311</sup> or differential scanning fluorimetry<sup>312</sup> could be helpful to compare the two isoforms of vitronectin and further verify the effect of rs704 on the protein structural conformation and stability.

### 5.3 AMD-associated rs704 Affects Vitronectin Binding to Cell Surfaces

Cell-binding experiments demonstrated that the AMD-associated VTN\_rs704:T isoform has a reduced ability to bind cell surfaces compared to the non-AMD-associated VTN\_rs704:C isoform. Again, these differences may be explained by local structural alterations initiated by rs704-related amino acid change at aa 400. Specifically, it has been reported that vitronectin interacts with cell surface glycosaminoglycans and proteoglycans through its heparin-binding site<sup>200,313,314</sup>, which is located within the third variable region of vitronectin at the C-terminus. This region also hosts the rs704 polymorphism encompassing amino acid 400<sup>195</sup>. The rs704-related amino acid change or the altered proteolytic cleavage of vitronectin, may induce different local conformational rearrangements of the protein within or near the heparin-binding domain, thereby affecting the ability of vitronectin to bind cell surfaces. Alternatively, vitronectin cell binding could be mediated by interaction with urokinase and integrin receptors *via* vitronectin-binding sites located at the N-terminal SMD and the RGD domains, respectively<sup>187,191</sup>, as well as with sulphated lipids and phospholipid lipids *via* the hemopexin domains of the protein<sup>174</sup>. Although these binding domains are relatively distant from the

rs704 site, it cannot be excluded that they may be structurally influenced by distal conformational changes of the vitronectin protein.

Altered cellular binding could significantly disrupt both the vitronectin-mediated physical anchoring of cells to the ECM and the regulation of receptor activation, resulting in changes in cell morphology, migration and signal transduction underlying cellular processes such as, for example, angiogenesis<sup>213,221,315</sup>. An imbalance in these processes could potentially contribute to the pathobiology of AMD.

#### 5.4 Vitronectin is Implicated in AMD-associated Processes

To investigate the functional differences of non-AMD risk-associated VTN\_rs704:C and AMD risk-associated VTN\_rs704:T and the putative contribution of vitronectin to AMD pathogenesis, the two isoforms of vitronectin were compared in their ability to regulate several cellular processes also implicated in AMD, in particular cell autophagy, viability, adhesion, migration and angiogenesis, as well as activation of ERK signalling<sup>209,234,272,316</sup>. These functional investigations involved cultured RPE and vascular endothelial cells, as dysfunction of these cell types *in vivo* has been observed in AMD<sup>317,318</sup>. Furthermore, in the retina, vitronectin protein was localised mainly within Bruch's membrane and the endothelium of chorioretinal vessels<sup>165</sup>.

Despite previous studies suggesting regulation of autophagy or cell viability by vitronectin and/or vitronectin receptors<sup>319-322</sup>, the functional experiments conducted in this thesis failed to show an effect of vitronectin on autophagy or cell viability. This might be attributed to the experimental approaches adopted in the present work, e.g., the time frames of exposure to vitronectin, the use of purified recombinant vitronectin in solution here instead of a uniformly distributed vitronectin coating on which the cells are seeded used in the literature cited, as well as the level and the type of cell stress induced (treatment with hydrogen peroxide here vs. ischaemic-reperfusion approaches or radiation exposure mainly used in the literature cited above). Moreover, these *in vitro* experiments do not exclude that vitronectin regulates these processes *in vivo*. Further experiments are required to elucidate the involvement of vitronectin in the regulation of these processes in the retina.

As part of the mitogen-activated protein kinase (MAPK) family, the ERK pathway mediates many aspects of RPE and endothelium homeostasis, including cell adhesion, proliferation, and production of angiogenic factors such as VEGF<sup>323-327</sup>. Furthermore, ERK dysregulation was implicated in the pathogenesis of AMD<sup>271,316</sup>. Specifically, the ERK signalling pathway is activated during AMD development. A comparison of transcriptomes from samples of normal human RPE-choroid and AMD-affected RPE-choroid demonstrated the activation of several signalling pathways, including ERK in AMD cases<sup>328</sup>. Also, human eyes with GA-AMD have shown activation of ERK that promotes RPE cell death<sup>271</sup>. In this thesis, the non-AMD risk-associated vitronectin isoform (VTN\_rs704:C) induced a statistically significant reduction in

ERK1/2 phosphorylation/activation in cultured RPE cells. A similar, though not statistically significant, effect was observed with the risk-associated VTN\_rs704:T isoform. This would suggest a role for this protein as a negative regulator of ERK activation in RPE cells with implications for the pathogenesis of AMD. Alterations in the inhibitory effect of vitronectin due to the rs704 risk variant (e.g., through increased vitronectin expression or reduced ability to bind cell surfaces) could alter the regulation of vitronectin-mediated ERK activation, causing an imbalance in ERK-mediated processes. Since ERK activation regulates both cell survival and apoptosis<sup>329,330</sup>, imbalances may favour cell death. Similarly, ERK-regulated cellular processes, such as cell adhesion, proliferation, and VEGF production<sup>323-327</sup> could be altered due to a potential rs704 risk variant-associated dysregulation of ERK signalling by vitronectin. In contrast, no effect of vitronectin isoforms on ERK regulation was observed in HUVECs, which is apparently in disagreement with previous findings<sup>331,332</sup>. Specifically, Jin and colleagues observed ERK activation after 5 and 10 min of HUVEC treatment with vitronectin. However, this activation gradually decreased over the subsequent 60 min. The authors hypothesised that such a stimulation may lead to the expression of the transcription factor AP-1 and of metalloproteinase MMP-9, which in turn play important roles in the later stages of angiogenesis<sup>331</sup>. In contrast, in HUVEC cells exposed to damaging radiation, vitronectin induced a suppression of ERK signalling with inhibition of radiation-induced p21 expression and subsequent protection of the cells from apoptosis<sup>332</sup>. It becomes evident that the effect of vitronectin *in vitro* is strongly influenced by the experimental conditions applied. Therefore, the concentration of recombinant vitronectin used in this study (1.5 µg/ml here vs. 10 or 50 µg/ml in the studies cited above) and the incubation time (24 h here vs. 5 to 60 min in the studies cited above) may have been unfavourable for the detection of a vitronectin-related effect. Together with the divergent literature available, the interpretation of the data obtained in this thesis remains difficult.

While the cell binding capacities of VTN\_rs704:C and VTN\_rs704:T showed significant differences, the two vitronectin isoforms exerted similar effects in cellular adhesion. Both vitronectin isoforms induced a strong binding of hiPSC-RPE and porcine RPE cells but did not affect adhesion to HUVECs. The apparent discrepancy between the effect on cell binding and adhesion could be explained by the fact that cell-binding assays reveal a physical interaction between vitronectin and cell membrane, which can be mediated by several cell surface molecules, such as lipids, various receptors, or heparin<sup>174,178,187,191,213,313,314</sup>. In contrast, adhesion is a cellular process involving the formation of specialized structures of multi-protein complexes built by cell adhesion molecules or receptors, ECM proteins and cytoplasmic plaques or peripheral membrane proteins<sup>333,334</sup>. Although stimulation of adhesion is a well-known property of vitronectin, which is consequently also frequently used as an adhesive for cells in culture<sup>335,336</sup>, in adhesion experiments with purified recombinant

vitronectin, the two vitronectin isoforms only stimulated adhesion of RPE cells but not of HUVECs. This could be explained by the interaction of vitronectin with PAI-1, a known angiogenic regulator and vitronectin binding partner<sup>287,337</sup>. As shown in this thesis and other studies<sup>338-340</sup>, HUVECs produce high amounts of PAI-1, to a much higher extent than ARPE-19 cells. Due to the proximity of the binding sites for PAI-1 and integrin/urokinase adhesion receptors on vitronectin, the binding of PAI-1 to vitronectin likely interferes with vitronectin-mediated cell adhesion through HUVEC cell surface receptors<sup>188,227,228,341</sup>. Conversely, ECMs containing VTN\_rs704:C or VTN\_rs704:T increased the adhesion of all cell lines tested including HUVECs. The increased attachment of HUVECs to the vitronectin-containing ECM could result from the compensation of the antagonistic effect of PAI-1 by other ECM components, such as collagen or fibronectin, which are alternative ECM cell-binding elements, and which, in this thesis, showed increased extracellular deposition by vitronectin-expressing cells (see following section 5.5).

Cell adhesion to vitronectin leads to the activation of integrin  $\alpha\beta3$  and enhances the activation of VEGFR-2 receptor by VEGF<sup>342-345</sup>. Furthermore, vitronectin increases the angiogenic activity of VEGF by direct binding<sup>221</sup>. This would allow vitronectin to positively regulate capillary formation and endothelial cell migration. However, migration and tube-formation assays performed within this thesis, showed that VTN\_rs704:C slightly reduced HUVEC migration, and both isoforms decreased tubulogenesis by HUVECs. The antagonistic binding of PAI-1 to vitronectin could again explain this observed slight anti-angiogenic effect of vitronectin. As reported in several independent studies<sup>228,346,347</sup>, pro-angiogenic activity of vitronectin can be impaired by PAI-1 which blocks vitronectin binding to the integrin receptor. Alternatively, the anti-angiogenic effect of vitronectin could be a consequence of its glycation profile<sup>348</sup>. Wang and colleagues demonstrated that advanced glycation of vitronectin (present after hyperglycaemia and in diabetes mellitus) inhibits VEGF-induced VEGFR-2 activation by uncoupling the VEGFR-2- $\alpha\beta3$  integrin crosstalk, resulting in reduced endothelial cell migration and vessel growth<sup>348</sup>. Recombinant proteins produced in mammalian expression systems are often considered identical, or at least very similar, to the native protein. However, differences in the glycan structures of specific proteins expressed in various mammalian cell lines have been reported<sup>349</sup>, which could, similarly to that described by Wang and colleagues, contribute to the anti-angiogenic effect of vitronectin. Finally, an indirect anti-angiogenic function attributed to vitronectin could be responsible for the observed anti-angiogenic effect. Yi and colleagues<sup>350</sup> reported that the presence of vitronectin supports the anti-angiogenic activity of substances such as osteonectin or angiostatin. This class of angiogenic inhibitors is derived from ECM and plasma proteins through proteolysis or other modifications and as such could potentially be a constituent of the matrices or media used during the experiments.

## 5.5 Vitronectin Induces Changes in ECM Resembling Those Associated with AMD

After heterologous expression in ARPE-19 cells for 4 weeks, vitronectin was deposited in the ECM in the form of large clusters, with a stronger extracellular accumulation of the AMD risk-associated VTN\_rs704:T isoform compared to the non-AMD risk-associated VTN\_rs704:C. This result is in line with the stronger expression of VTN\_rs704:T than VTN\_rs704:C observed in this and other studies <sup>243</sup>.

Interestingly, the presence of the two vitronectin isoforms in the ECM increased deposition and clustering of main structural ECM constituents, such as fibronectin, collagens, and elastin, also with a stronger effect of VTN\_rs704:T than VTN\_rs704:C. Vitronectin is known to interact with many ECM components, e. g. heparin, glycosaminoglycans, and collagens <sup>351-353</sup>. Larger amounts of deposited vitronectin might therefore bind larger amounts of collagen, possibly leading to the observed collagen aggregation at the vitronectin deposition site. In line with this, it has recently been reported that vitronectin accelerates collagen fibril formation and morphological changes by binding to collagen under neutral conditions <sup>354</sup>. Interestingly, in this study, an alternative mechanism was uncovered by which vitronectin would increase collagen in the matrix, namely by binding to and inhibiting the activity of cathepsin K, which is responsible for collagen degradation <sup>354</sup>. Collagen, in turn, interacts with fibronectin and stimulates the formation of a stable fibronectin network <sup>355-358</sup>. Increased collagen deposition might thus explain the observed increase in fibronectin in matrices containing vitronectin. Alternatively, vitronectin can directly influence fibronectin deposition. As described by Pankov and colleagues <sup>359</sup>, it may enhance fibronectin polymerisation into fibrillar structures through binding to the  $\alpha 5\beta 1$  integrin receptor. However, this hypothesis is less well established, as *in vitro* studies have also shown that vitronectin can inhibit fibronectin deposition in the ECM <sup>360-363</sup>. Fibronectin in turn is reported to bind elastin <sup>364</sup> and promote its deposition, which can explain the increase in elastin deposition in vitronectin-containing matrices as observed in this thesis. With ageing and particularly during AMD development, the structure of Bruch's membrane undergoes changes including calcification and increased stiffness <sup>210</sup>. The accumulation of structural elements, mainly collagen, and their cross-linking contribute to an increase in Bruch's membrane thickness and worsens diffusion of nutrients and waste to and from the retina, affecting RPE metabolism and drusenogenesis <sup>89,210,365</sup>. The observed ability of vitronectin to increase the deposition and clustering of ECM structural constituents, may suggest a potential contribution of vitronectin and rs704 in AMD-associated ECM structural alterations. In line with this, recent evidence suggested that vitronectin is the coordinator of calcium mineralisation in AMD-associated extracellular sub-RPE deposits <sup>202</sup>.

The ECM of ARPE-19 cells containing vitronectin isoforms also revealed an increase in complement components C9 and CFH. This appears of considerable biological interest since

dysregulation of the complement system is a significant driver of AMD pathogenesis<sup>134</sup>, and AMD-associated deposits also contain components of the complement pathway, including C9 and CFH<sup>40,41,47,366</sup>. Vitronectin is a well-established binding partner of C9<sup>196,203,367,368</sup> which could explain the increase of C9 in ECMs containing vitronectin isoforms. Alternatively, the expression of C9 and CFH may be altered by vitronectin-induced changes in the ECM. Indeed, it has previously been reported that structural changes in the ECM significantly affect gene expression and protein secretion profiles of the RPE, especially concerning components of complement or growth factors, including VEGF and PEDF<sup>101,134,369</sup>. Of note, CFH and its truncated isoforms are the main negative complement regulators that binds ECM, including Bruch's membrane, to prevent excessive complement activation and inflammation<sup>370-372</sup>. Interestingly, analysis of the ECM deposited by ARPE-19 also showed a positive correlation between deposition of vitronectin isoforms and VEGF accumulation. In primary human RPE cells, CFH synthesis was shown to be stimulated by VEGF<sup>373</sup>, thus increased VEGF may also be causative for the enhanced deposition of CFH observed in vitronectin-containing matrixes.

In addition to its expression being influenced by alterations in the ECM, localisation and function of the angiogenesis-stimulating factor VEGF are closely dependent on its binding to ECM components<sup>106,374,375</sup>, including vitronectin, which in its multimeric form binds VEGF<sup>221</sup>. The direct binding of VEGF to vitronectin could explain VEGF increase in the vitronectin-containing matrixes deposited by ARPE-19. Alternatively, the increase in matrix-bound VEGF can also be attributed to an increase in the deposition of other components of the ECM capable of binding VEGF in the vitronectin-containing matrixes, such as fibronectin which was shown to directly interact with VEGF<sup>376,377</sup>.

Taken together, the observed alterations in ECM composition could contribute to a disturbance of the pro- and anti-angiogenic balance that, in AMD, seems to be triggered by changes in Bruch's membrane, together with complement system hyperactivity and inflammatory responses<sup>210</sup>. This finding would support a novel role for vitronectin in the pathobiology of AMD beyond its acknowledged involvement in AMD-associated deposit formation<sup>166,202</sup>.

## **5.6 Vitronectin and PAI-1 Interaction may Contribute to Vascular Complications in AMD**

The interaction of vitronectin with angiogenic regulator PAI-1 is among the best-characterised physical interaction of vitronectin with extracellular proteins<sup>185,287,288</sup>. As a member of the serine protease inhibitor (serpin) superfamily with anti-protease activity, PAI-1 is the main physiological inhibitor of tissue-type (tPA) and urokinase-type (uPA) plasminogen activators. Besides being crucially involved in fibrinolysis and wound healing, PAI-1 plays a key role in various acute and chronic pathophysiological processes, including those involving

vascular complications in AMD <sup>289-291,337</sup>. Indeed, PAI-1 regulates a variety of angiogenesis-related processes, including pericellular proteolysis, cell migration, adhesion, and reattachment <sup>378-380</sup>. Its half-life is closely dependent on its binding to vitronectin, which through allosteric modulation stabilizes the active state of PAI-1 by slowing its conversion to an inactive state <sup>226</sup>.

In this thesis, co-precipitation experiments showed that the AMD risk-associated VTN\_rs704:T isoform bound stronger to PAI-1 than the non-AMD risk-associated VTN\_rs704:C. This contrasts with findings of Gibson and colleagues, who suggest that rs704 has no impact on vitronectin binding to PAI-1 <sup>208</sup>. Their study, however, used a truncated version of VTN\_rs704:C, lacking the short-chain peptide of the rs704-dependent protein cleavage product, which *in vivo* remains bound to the protein by disulphide bonds <sup>381,382</sup> and probably affects its folding or accessibility to PAI-1. Similarly, rs704-related amino acid change (T400M), which causes altered folding and processing of vitronectin <sup>237,239</sup> may affect the accessibility of the interaction site with PAI-1 and result in stronger binding of VTN\_rs704:T to PAI-1. Alternatively, since the binding of vitronectin to PAI-1 results in the incorporation of vitronectin monomers into a higher-order complex <sup>383,384</sup>, the differences between the two vitronectin isoforms in their binding to PAI-1 could also reflect a different promotion of self-association of the two vitronectin isoforms by PAI-1. This could result in a difference in the number of vitronectin monomers complexed and thus retained by immobilised PAI-1.

While the two isoforms differed in their ability to bind PAI-1, they showed no difference in their capacity to stabilize the active state of PAI-1. This apparent discrepancy could be attributable by the different experimental approaches. The co-precipitation assay measures the stable physical interaction between vitronectin and PAI-1. In contrast, the enzymatic assay measures the capacity of vitronectin to stabilize the active form of PAI-1. It was described before that a stable interaction between two biomolecules is not necessarily a requirement for enzymatic processes. For example, rhomboid proteases cleave their substrate very efficiently without showing apparent binding affinity <sup>385</sup>. Similarly, stable binding between vitronectin and PAI-1 may not be relevant for the stabilization of active PAI-1 and the enzymatic assay may thus also detect less stable, unstable, or perhaps even transient interactions. Alternatively, different sensitivities of the two experimental approaches or a saturation effect in the enzyme assay may explain the apparently conflicting results.

In this thesis, the addition of recombinant isoforms of vitronectin significantly increased the expression of PAI-1 protein in HUVECs and ARPE-19 cells and their ECM. Consistently, Preissner and colleagues showed that vitronectin from cultivation medium associates with HUVEC-deposited ECM, where it represents the main binding component for PAI-1 <sup>386</sup>. Furthermore, increased deposition of endothelial PAI-1 by human umbilical artery endothelial

cells (HUAECs) and HUVECs cultured on vitronectin-coated surfaces, compared to other ECM substrates, was reported <sup>387,388</sup>. In this thesis, there was a similar trend towards an increase in PAI-1 protein level in cells and ECM after exposure to VTN\_rs704:T compared to VTN\_rs704:C, although this was not statistically significant. Since PAI-1 transcription in HUVECs remained unchanged after vitronectin exposure, the increase in the amount of PAI-1 protein could be attributed to posttranslational processes rather than to increased expression. A mechanism by which vitronectin prevents PAI-1 degradation has been described in cultured blood monocytes <sup>389</sup>: When bound to vitronectin, active PAI-1 undergoes a conformational change that makes it less accessible to proteolytic enzymes. In addition, the observed increase of ECM-bound PAI-1 in the presence of vitronectin could also be explained by the ability of vitronectin to translocate PAI-1 into the ECM <sup>390</sup>. Furthermore, it has been reported that active PAI-1 is internalised when complexed with uPA *via* receptor-mediated endocytosis <sup>389,391</sup>. Since vitronectin stabilises the active PAI-1 conformation, this could explain the increase in the cellular amounts of PAI-1 after incubation of HUVECs with vitronectin. Finally, the increase in extracellular amounts of PAI-1 promoted by vitronectin-mediated proteolytic protection <sup>389</sup> could also lead to increased binding of PAI-1 to the cell surface of HUVECs, e.g., *via* the low-density lipoprotein receptor-related protein (LRP) <sup>389,392</sup>, again explaining the increased amounts of PAI-1 in the cellular fractions of HUVECs in this study.

In various pathologies, including cellular necrosis and inflammation, fibrosis, and vascular atherosclerosis <sup>393-397</sup>, PAI-1 and vitronectin localise and act together at the sites of injury. In the retina, vitronectin might concentrate and coordinate local PAI-1 in the vicinity of endothelial and RPE cells. In addition, vitronectin could potentially be a vehicle for PAI-1 from the bloodstream, given that PAI-1 in blood mainly circulates in a complex with plasma vitronectin <sup>287,398</sup>. Specifically, due to vitronectin transcytosis by vascular endothelial cells <sup>399</sup>, vitronectin could direct complexed PAI-1 from the bloodstream into the subendothelial matrix as well as into the extracellular space adjacent to the RPE. The extent of the translocation of PAI-1 into the ECM by vitronectin may depend on the rs704 genotype: As a result of its high concentration and/or the increased ability to bind PAI-1 observed in this thesis, the AMD-associated isoform of vitronectin could further promote the amount of PAI-1 in the ECM and broaden the spectrum of its activity in AMD. Altered retinal concentrations of PAI-1 can simultaneously result in alterations of ECM proteolysis <sup>224</sup>. The prevention of ECM degradation, exerted through PAI-1 inhibition of uPA proteolytic activity, could be inappropriately sustained by increased levels of PAI-1 with an impairment of balance between ECM synthesis, degradation, and turnover. This could lead to stiffness of the ECM in both the perivascular microenvironment and Bruch's membrane and create a hypoxic stimulus that could initiate/worsen cellular and extracellular defects associated with AMD,

including abnormal neovascularisation<sup>211,400,401</sup>. Similar changes were reported in transgenic mice that overexpress human PAI-1 in retinal microvasculature<sup>402</sup>. In this context, hypoxia may also result from excessive inhibition of fibrinolysis associated with elevated PAI-1 levels<sup>402</sup>, which by contributing to transient narrowing of the retinal capillary lumen<sup>402</sup> may induce microvascular dysfunction and ischemia potentially causing neovascularization in AMD<sup>401,403,404</sup>. Excessive inhibition of PAI-1-dependent ECM degradation and turnover could also explain the above-discussed general increase in ECM deposition observed in the presence of vitronectin. In addition to exacerbated PAI-1 anti-protease activity, a vitronectin-dependent increased concentration of PAI-1 may alter any of the cellular events controlled by this protein and involving cell surface receptors, such as cell attachment, migration, proliferation, angiogenesis as well as regulation of related intracellular signalling<sup>213,405,406</sup>. In line with this, it has been discussed that in excess of PAI-1, the vitronectin matrix remains saturated with PAI-1 resulting in an impasse of integrin-mediated vascular cell adhesion<sup>407</sup>.

Together with previous reports on the mutual involvement of PAI-1 and vitronectin in angiogenesis<sup>341,408</sup> and neointima formation<sup>397</sup>, the results of this thesis would support a role of this protein interaction in the vascular complications of AMD. PAI-1 per se has already been reported in the pathogenesis of neovascular AMD<sup>289-291</sup>.

Interestingly, the refinement of the association analysis of rs704 with clinical subtypes of AMD in the IAMDGC dataset, performed in a collaboration with Dr. Christina Kiel (Institute of Human Genetics, University of Regensburg), revealed that the association of rs704 with advanced AMD only exist with the neovascular subtype<sup>292</sup>. This supports a new potential role for vitronectin in the pathogenesis of AMD, not only limited to the formation of drusen or subretinal drusenoid deposits.

Finally, the rs704 risk genotype-dependent increase in the concentration of vitronectin (and the associated PAI-1) can be aggravated by age-dependent alterations in gene expression. A large-scale gene expression analysis conducted in a collaboration with Dr. Tobias Strunz (Institute of Human Genetics, University of Regensburg) revealed a statistically significant increase in *VTN* and *PAI-1* mRNA expression in blood samples and retinal tissues from healthy donors aged 60 years and older<sup>292</sup>. Furthermore, this analysis showed a positive correlation between *VTN* and *PAI-1* gene expression, which suggests that the two genes are subject to similar mechanisms of transcriptional regulation, possibly influenced by ageing<sup>292</sup>.

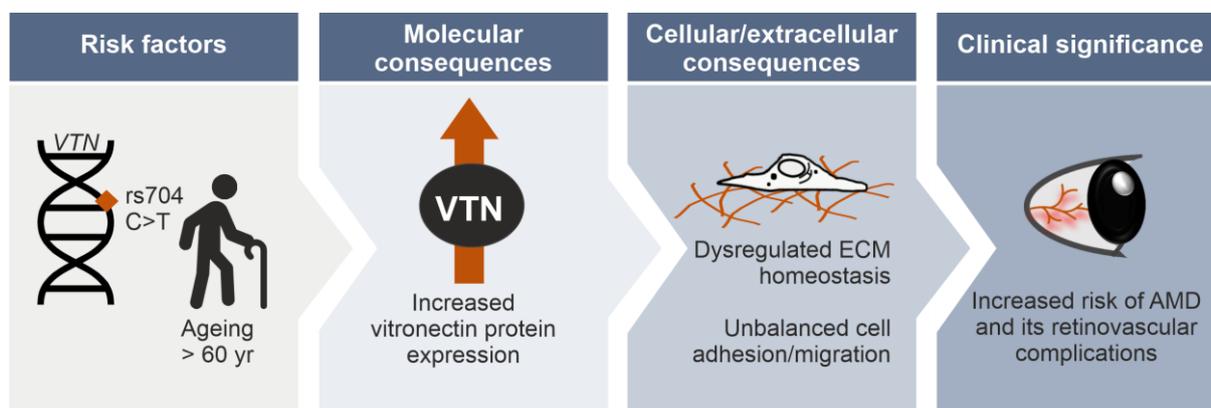

## 5.7 Conclusion: rs704-related AMD Disease Model and Its Clinical Implication

In conclusion, the results of this thesis further provide support for the involvement of vitronectin in the pathogenesis of AMD but also highlight possible new pathways through which this protein could contribute to AMD development and progression. The presented findings suggest a conceptual disease model for AMD (**Figure 36**), according to which the rs704 risk genotype, in combination with advanced age, leads to a significant increase in

protein expression of vitronectin in the retina (and in the systemic circulation <sup>243</sup>). This, in turn, could lead to an imbalance in the various cellular and extracellular processes regulated by vitronectin, e. g. a dysregulation in the organisation and turnover of the endothelial basement membrane/Bruch's membrane, in the storage and activity of angiogenic regulators such as VEGF and PAI-1 and, consequently, in cellular processes such as cell adhesion and migration. This altered homeostasis might promote or worsen AMD-associated pathological events, in particular neovascular complications.

In recent years, therapies targeting integrins (including vitronectin receptors) have shown positive results in the treatment of retinovascular disease, and several integrin inhibitors are currently in clinical trials <sup>409,410</sup>. For instance, JNJ-26076713 (Johnson & Johnson) is a potent, orally bioavailable inhibitor of  $\alpha\beta3$  and  $\alpha\beta5$  binding to vitronectin. Treatment with JNJ-26076713 reduced neovascularisation and retinal vascular permeability in an animal model of oxygen-induced retinopathy and is currently undergoing preclinical study. SF-0166 (SciFluor Life Sciences), a small molecule inhibitor of the vitronectin  $\alpha\beta3$  receptor, inhibited cell adhesion to vitronectin and reduce neovascularisation *in vitro* <sup>411</sup>, and was already effective in clinical phase 1/2 in reducing retinal thickening and improving visual acuity (<https://clinicaltrials.gov/ct2/show/NCT04746963>). However, while these molecules appear highly effective, one of their limitations is their poor selectivity, as they often inhibit other non-target  $\alpha\beta$  integrins to varying degrees with possible side effects <sup>410</sup>.

Embracing the emerging literature suggesting vitronectin as a promising therapeutic target for the treatment of AMD <sup>202,412</sup>, the results of this work would suggest an alternative therapeutic approach in which therapeutic modulation of vitronectin protein expression through genetic or pharmacological approaches could, for example, help restore vascular/retinal homeostasis and prevent its decline in AMD development. Furthermore, as a molecular marker, rs704 can be used to develop clinical prevention studies targeting unique subgroups of people at increased risk of developing AMD. Hence, additional research to fully understand the pathogenicity of vitronectin isoforms and their management could be valuable for the comprehension and treatment of AMD.

## **Acknowledgements**

This doctoral thesis would not be complete without properly thanking my supervisor, Prof. Dr. Bernhard Weber, for welcoming me to the Institute of Human Genetics at the University of Regensburg, giving me the great opportunity to work in his team and live an experience of both scientific and personal growth. In particular, I am very grateful for his continuous support in all aspects of my thesis, which together with his immense enthusiasm and knowledge in this field of study, helped, taught and inspired me a lot to pursue this project with hard work and dedication.

I would like to thank my mentors, Prof. Dr. Veronica Egger and Prof. Dr. Selim Corbacioglu, for their time and helpful comments and suggestions.

Special acknowledgement goes to the PRO RETINA Deutschland e. V. Foundation for contributing financially to this research.

I am very thankful to my group leader, Dr. Ulrike Friedrich, who from the very beginning of my doctoral project made her time and professional expertise available to me, providing me with a valuable support in planning experiments, evaluating data, or writing and designing presentations, poster, and manuscripts.

My gratitude goes to Martina Esser, for her precious technical assistance, for her support and friendship.

I wish to acknowledge my colleagues, Dr. Tobias Strunz and Dr. Christina Kiel, for sharing their professional experience and bioinformatics knowledge in a nice and fruitful collaboration for the purposes of this project. Thanks also for the many productive discussions on my research.

I would like to thank my colleague Dr. Karolina Plössl, for lending me her experience and intuition for my scientific and technical doubts especially at the beginning of this project, but also for brightening my days with delicious cakes.

A special thanks to Verena Schmid, who from day one has been an extraordinary base of support, a friend and an ideal office and laboratory mate in the most enjoyable moments but also in the most stressful ones.

To all the dear colleagues and students at the Institute of Human Genetics who, regardless of whether they were involved in this project or not, have enriched my daily life intellectually and humanely over the years, I say thank you for everything, but above all for always making me feel at home in a warm and stimulating atmosphere.

Last but not least, I would like to thank my family and all my friends for the encouragement they have given me. Though my biggest thanks go to Andrea, my husband to be and best friend, who with his love, patience and positivity has helped me through this challenging time. Grazie ami, dal profondo del mio cuore.

**Selbständigkeitserklärung**

Ich, Biasella Fabiola geboren am 04.04.1990 in Isernia (Italien), erkläre hiermit, dass ich die vorliegende Arbeit ohne unzulässige Hilfe Dritter und ohne Benutzung anderer als der angegebenen Hilfsmittel angefertigt habe.

Die aus anderen Quellen direkt oder indirekt übernommenen Daten und Konzepte sind unter Angabe der Quelle gekennzeichnet. Insbesondere habe ich nicht die entgeltliche Hilfe von Vermittlungs- bzw. Beratungsdiensten (Promotionsberater oder andere Personen) in Anspruch genommen.

Die Arbeit wurde bisher weder im In- noch im Ausland in gleicher oder ähnlicher Form einer anderen Prüfungsbehörde vorgelegt.

Regensburg,
